Other special-status species documented at Lake Merced include western pond turtle sightings in East Lake and a California red-legged frog sighting in Impound Lake in 2000 (SFRPD 2006). California red-legged frog has not been observed since a single sighting in 2000 and prior to that had not been observed since the 1970's (SFPUC 2011). Based on the lack of sightings, negative protocol-survey results from 2000, and the presence of bullfrogs and largemouth bass, red-legged frog were considered extirpated from Lake Merced (SFRPD 2006; San Francisco Planning Department 2011; SFPUC 2011) and, with no evidence to the contrary, are presumed extirpated for the purposes of this analysis.

It is presumed that western pond turtle are still present in East Lake, although the presence of red-eared sliders and bullfrogs was considered a threat to the population over five years ago (SFRPD 2006) and they may have been extirpated since that time. It is unknown whether suitable western pond turtle nesting habitat is present at Lake Merced but it would be most likely to occur in dry sandy to hard soils on low gradient slopes with low, sparse vegetation (Jones and Stokes 2004). Suitable nesting sites can occur as far as 300 feet from the water line (CDFG 2000) but are typically much closer and could thus be vulnerable to inundation. Females move from aquatic sites to upland sites that are usually located above the floodplain (or in this case, above the highest average annual water level) and can lay their eggs, sometimes more than one clutch, anywhere between April and August, although most oviposition occurs in April and May. Nests must be dry (Jones and Stokes 2004) but also have a relatively high internal humidity for eggs to develop and hatch properly (CDFG 2000). Incubation can last up to three months and hatchlings typically overwinter in the nest, emerging the following spring (Jennings and Hayes 1994).

---

[22]Nests that are not yet supporting eggs can be rebuilt and chicks of all the species in question are precocial, meaning they are capable of a high degree of independent activity immediately after hatching and can leave the nest and be relocated by their mother in response to fluctuations in water level.

Loss of potentially suitable turtle nesting habitat due to inundation by rising water levels would not be considered significant, since the majority of soils surrounding East and North Lakes are sandy (SFRPD 2006) and even at the maximum possible water surface elevation of 13 feet, sufficient habitat would remain to support ongoing western pond turtle reproduction. Pond turtles typically nest close to the water line but above areas prone to inundation. Since nests must be relatively dry, it would be expected that pond turtles would typically choose nest sites at least three feet above the annual high water level in any given year, so gradual increases in water surface elevations over time would not be expected to impact nesting pond turtles. Similarly, water surface elevation decreases, whether gradual or by several feet in less than a year would not impact nesting pond turtles as their nests would remain above water. However, loss of occupied nesting habitat inundated during a single year such that turtle eggs or nestlings were lost could threaten the Lake Merced western pond turtle population, if it still exists, and would therefore be considered a significant impact.

Adverse Effects on Rare Plants and Sensitive Communities

Rare plants

There are four special-status plant species documented recently at Lake Merced: San Francisco spineflower, San Francisco wallflower, blue coast gilia, and dune tansy (May & Associates 2009; Nomad Ecology 2011). In addition, there are seven plant species of local concern that occur at Lake Merced: California pipevine, Wight's paintbrush, Vancouver rye, wild cucumber, canyon live oak, coastal black gooseberry, and thimbleberry (May & Associates 2009; Nomad Ecology 2011). See Figure 5.14-2 (Lake Merced Sensitive Habitats and Species) in Section 5.14.1 [Setting] for locations of rare plants and sensitive plant communities.

None of these eleven species are federally or State listed, three are listed by CNPS, and the rest are listed by CNPS as locally rare and significant in the CCSF. Normally, only federal, State, and CNPS List 1 and 2 species are considered under CEQA. However, all eleven species noted occur in coastal dune scrub and coastal scrub habitat types, further described below, which have been severely reduced from their original extent within the CCSF.

Because special-status plants and their habitat are locally rare and thus at high risk of local extinction, impacts on rare plant habitat at Lake Merced would be considered significant under CEQA. All of these plant species occur outside the Lake Merced watershed and most are more common elsewhere throughout their range and extirpation of a local population would not pose a risk to the overall survival of the species. Given this context, some habitat loss could be acceptable and result in a-less-than significant impact under CEQA. However, due to the general lack of local habitat,, a relatively low threshold for loss is appropriate for this CEQA analysis, and impacts on special-status plant habitat would be considered significant for the purpose of this EIR if an increase in average lake levels were to result in the loss of more than 10 percent of occupied habitat, as mapped by the SFRPD (SFRPD 2006), May & Associates (May & Associates 2009), and Nomad Ecology (Nomad Ecology 2011), for one or more of the special-status or locally sensitive plants known to occur at Lake Merced.

Sensitive Communities

The following have been identified as sensitive vegetation and habitat types at Lake Merced: Central dune, thimbleberry, wax myrtle, and canyon live oak scrubs, Vancouver rye grassland (perennial grassland), fish-related habitat, wetlands (including arroyo willow riparian scrub), and blue gum eucalyptus forest. Arroyo willow riparian scrub is discussed below under wetlands and eucalyptus forest is discussed below under wildlife nursery sites.

*Central Dune Scrub***.** While there were no stands of dune scrub mapped at Lake Merced in 2002 (SFPRD 2006), restoration efforts have resulted in the establishment of over 3 acres of this vegetation type, which is rare on the San Francisco Peninsula. Dune scrub is not only locally rare, but also supports several rare plant species at Lake Merced, including San Francisco spineflower, Wight's paintbrush, dune tansy, and San Francisco wallflower and is therefore considered sensitive as rare plant habitat for the purposes of this EIR.

Locally sensitive coastal scrub types. The classification of coastal scrub at Lake Merced encompasses several different subtypes that are dominated by locally rare plant species and therefore considered sensitive natural communities for the purposes of this analysis. These subtypes include thimbleberry scrub, wax myrtle scrub, and canyon live oak scrub. These vegetation types occur in only one or two locations around Lake Merced (see Figure 5.14-2 [Lake Merced Sensitive Habitats and Species] in section 5.14.1 [Setting]) as well as in other parts of the CCSF (SFRPD 2006; CNPS 2011).

Vancouver rye grassland. This is a perennial grassland dominated by Vancouver rye, which is a hybrid between American dunegrass and creeping wild rye and thus reflective of both the dune and riparian ecological history of Lake Merced. At last report, this grassland occurred in one location on the north shore of East Lake at the base of a steep slope and adjacent to blue gum eucalyptus forest and rush meadow (Nomad Ecology 2011). Vancouver rye grassland was considered sensitive due to its local rarity by the SFRPD (SFRPD 2006) and the species is considered locally rare by CNPS. Therefore, impacts on this vegetation type would be considered significant.

Fisheries and Fish Habitat

The open waters and emergent wetlands of Lake Merced provide aquatic habitat, cover, and foraging habitat for a variety of native and non-native fish. Twenty-seven species have been collected there over the years, 18 of which are native species. Tidewater goby, a federally endangered species, are known to have occurred historically (1894) but are now presumed extirpated (CDFG 2011e). Several other species, including starry flounder, staghorn sculpin, and topsmelt, may have been present at least intermittently when Lake Merced was hydrologically connected to the ocean. At least 11 species have been introduced to the lake since 1893 and the most abundant species in recent studies were introduced largemouth bass and Sacramento blackfish (LMTF 2007). There is no spawning habitat for rainbow trout so this species must be stocked in order to maintain a fishery and stocked adults persist in the lake for only a short time. Native fishes with currently self-sustaining populations at Lake Merced include: tule perch, prickly sculpin, Sacramento blackfish, and threespine stickleback. Non-native fishes with self-sustaining populations include largemouth bass, common carp, and goldfish (LMTF 2007). There currently are no special-status fish species found in Lake Merced.

In 2004, the SFPUC retained EDAW (a San Francisco-based environmental consulting firm that is now part of AECOM) to assess the effect of water level rise on Lake Merced fisheries. EDAW's analysis anticipated that the greatest potential effect would come from reductions in littoral habitat (defined as areas with three feet or less of water around the lake perimeters) with rising lake levels, using a study baseline of 0.5 feet City Datum (EDAW 2004). The EDAW study has been reviewed by the preparers of this EIR and the study's methodology and conclusions have been determined to be adequately supported by the information presented therein. However, it was predicted that most of the loss would be in Impound Lake and much of this loss has already occurred. Decreases in littoral area were expected to impact warmwater species. But the EDAW study found that littoral area was already a very small component of the overall lake habitat, and that since there were other factors more likely to control warm water species (i.e., temperature, cover, and water clarity), this change was expected to have minimal impacts on warmwater fish population abundance, growth rates, or ability to reproduce. The EDAW study did not expect coldwater fish species to be affected by lake level increases. Water level decreases could result in increases of littoral habitat, at least to begin with, by regaining habitat lost when lake levels rose from the EDAW study baseline of 0.5 feet City Datum, and eventually, reductions in coldwater habitat through rising water temperatures, which could increase warmwater and reduce coldwater fish populations, respectively. Coldwater fish at Lake Merced are trout, which are not self-sustaining and are regularly stocked and prickly sculpin, which as of 2007 appeared to be self-sustaining (LMTF 2007). The remaining fish are warmwater species.

As described above, there are no special-status fish in Lake Merced, and the species most important for recreational purposes are regularly stocked; however, if decreased water levels were to cause fish populations to drop below levels needed to sustain the local bird populations that rely upon them—which include special-status and otherwise protected birds—the impact could potentially be significant. Population numbers for fish-eating birds as well as fish at Lake Merced are presently unknown. The Lake Merced Task Force Fish Community Study (LMTF 2007) noted that cormorants were not documented as nesting at Lake Merced prior to 1997 and that nest numbers increased from 18 in 1997 to around 200 in 2004. In 2007, 11 great blue heron and 319 double-crested cormorant nests were documented at Lake Merced and their increase in numbers may be attributable to lake level rises over low levels seen in the 1970's through the 1990's and consequent improvements in habitat (GGAS 2007). This conclusion would be speculative though, since no definitive studies have been conducted on fish population numbers or the foraging habits of fish-eating birds at Lake Merced. Nesting cormorants have been documented as flying to and from the ocean to forage while nesting at Lake Merced, which suggests that they, and presumably other fish-eating birds present at Lake Merced, do not depend exclusively on the fish available in Lake Merced (LMTF 2007). As noted above, the health of Lake Merced's fisheries is closely tied to availability of littoral habitat and water quality also plays an important role. These factors are likely the main drivers of fish abundance in Lake Merced and can be tied to the lake's beneficial uses.

The San Francisco Bay RWQCB defines several fish-related beneficial uses for Lake Merced: cold freshwater habitat, warm freshwater habitat, and fish spawning. A substantial degradation or loss of these beneficial uses, for example through significant changes in water temperature, loss of littoral habitat, or reduction in dissolved oxygen, would be considered significant. EDAW (EDAW 2004) assessed potential impacts on beneficial uses in relation to lake level rise up to 8 feet City Datum and water inputs from various potential sources and found that no effects on beneficial uses were expected. Similarly, as noted in Section 5.16, Hydrology and Water Quality, no significant correlation between lake levels and water quality has been identified in recent years, when lake levels were rising or stable. However, as also noted, and explained in greater detail, in Section 5.16, Hydrology and Water Quality, lake levels below 0 feet City Datum could result in adverse impacts on water quality through a variety of mechanisms, such as increased sedimentation due to erosion of exposed sediments or reductions in dissolved oxygen due to increased algal growth and eutrophication, and these impacts could have a substantial adverse effect on Lake Merced's beneficial uses related to fish habitat, and therefore fish populations and, indirectly, fish-eating bird populations, which, depending on the magnitude, duration, and frequency of the effect, could potentially be a significant impact.

Adverse Effects on Wetlands

As the only remaining large coastal lake and wetland between Pescadero to the south and Point Reyes to the north, Lake Merced provides valuable wildlife habitat, especially for birds. The lake's wetlands and willow riparian scrub provide wintering habitat for thousands of birds, resting and foraging habitat for fall and spring migrants, and are used as breeding and feeding habitat for nearly 50 species. The lake's wetlands also provide cover, foraging habitat, and nursery sites for warmwater fish as well as cover and foraging habitat for western pond turtle. Impacts on wetlands resulting from changing water levels could include direct wetland losses. Indirect effects due to water quality degradation at low water surface elevations are not expected to significantly affect wetland vegetation since healthy wetland vegetation has been maintained in the past at lower water levels. For example, the extent of bulrush wetlands was greater in 1996 (SFRPD 2006) and 2002 (Nomad Ecology 2011), with a mean water surface elevation of 0.5 feet City Datum, than they are today.

The slopes surrounding Lake Merced currently support approximately 27 acres of willow riparian scrub (see Table 15.4-4 [Lake Merced Vegetation Acreage: 2002, 2010, and 2012]). Since most of the willow scrub habitat at Lake Merced would also be considered jurisdictional wetlands, impacts on willow scrub are considered as part of the wetlands impact. This vegetation community is common throughout central and coastal California and as such is not always considered a sensitive natural community. However, willow scrub at Lake Merced provides high quality riparian habitat for a variety of special-status and common birds and is therefore considered sensitive by CDFW and RWQCB. In addition, the California Coastal Commission often considers willow scrub as an Environmentally Significant Habitat Area, whether or not it also has wetland status.

Lake level rise since 2002 has resulted in the conversion of a little over 1.5 acres of willow scrub to open water (see Table 15.4-4 [Lake Merced Vegetation Acreage: 2002, 2010, and 2012]) and further rise in lake levels is predicted to reduce the extent of this vegetation type. However, losses could be ameliorated somewhat through movement of willow upslope, as has also been observed since 2002 (Nomad Ecology 2011). Similarly, lake level reductions would allow willow scrub to move down slope with falling water levels.

Because habitat at Lake Merced would be considered wetlands by the USACE and/or CDFW and RWQCB (see Section 5.14-2 [Regulatory Framework]), the federal and State no-net-loss policies described in the Section 5.14-2 would reasonably be applied to the proposed Project when determining the significance of impacts on wetlands as may be caused by the Project.

Adverse Effects on Wildlife Nursery Sites

Large eucalyptus along the shores of North and South Lakes support several double crested cormorant and great blue heron rookeries, and red-shouldered and red-tailed hawks nest in large trees (eucalyptus, Monterey cypress, and pines) around all of the lakes (SFRPD 2006). Although red-shouldered and red-tailed hawks nest in parks throughout the City, heron rookeries are found only at Lake Merced and Stow Lake, with one small colony reported at the Palace of Fine Arts that may have since been extirpated (Kelly et al. 2006). In May, 2012, several rookery trees were located in the same general areas as previously mapped (SFRPD 2006) and most were approximately 1 to 5 feet above the water surface elevation, which was at or near its seasonally highest level of approximately 6.5 to 7 feet City Datum. Inundation for more than a month is expected to kill individual upland trees, which would reduce nesting substrate for herons, cormorants, and hawks. Results of the 2012 vegetation mapping update, described below, show that there are a total of 50.5 acres of non-native forest around Lake Merced, including nearly 18 acres of eucalyptus. As noted above, red-tailed and red-shouldered hawks nest in parks, open space, and some residential areas throughout the CCSF (SFFO 2003) and therefore, with relatively abundant nesting substrate available to raptors elsewhere, the loss of non-native forest at Lake Merced would not be considered significant for raptors.

Rookery trees typically die over time due to bird use and buildup of 'whitewash' on their branches. When a tree dies completely, the birds typically move their nests to an adjacent tree (USFWS 2011b) so the death of individual trees in and of itself is not considered significant. However, the distance from disturbance is typically important for nesting herons and a buffer of at least 300 feet is recommended (VFWD 2002). The rookery trees on North and South Lakes are about 80 feet and 200 feet, respectively, from busy roadways and a well-used walking trail. The third rookery, on East Lake, is more isolated and less prone to disturbance.

Since eucalyptus are an upland species, with distribution not tied to water levels, and the upper limits of most eucalyptus habitat are determined by adjacent roadways, this habitat type is not expected to move upslope with increasing water levels and would thus be permanently lost. Lake level reductions are not expected to impact rookery trees since wetlands would 'migrate' downslope along with gradually falling water levels and the trees would still be proximate to wetland and open water foraging habitat.

Predicted rises in water levels under modeled existing conditions would likely result in loss of rookery trees and other eucalyptus that provide potential alternate nesting substrate for great blue herons and cormorants below 12.4 feet City Datum. The rookery trees at South Lake would be expected to be lost with a rise in annual average water surface elevation to 7 feet City Datum but the eucalyptus stand that supports the rookery is likely large enough that the rookery could move to adjacent trees further upslope and still remain buffered from the roadway and pathways. The trees at North Lake would be inundated with a rise in annual average water surface elevation to 6.5 feet City Datum. Loss of these trees would likely require the rookery to move to a different area as there would be no buffer trees left. The rookery trees at East Lake would not be impacted as they are located at an approximate elevation of 20 feet City Datum.

Although rookeries are locally rare, there is sufficient eucalyptus forest present at Lake Merced to sustain the rookeries there should small losses of mature eucalyptus occur. In this case, there would still be sufficient trees located at sufficient distance from human disturbance to allow for the rookeries to move from one tree to another. Larger losses of eucalyptus forest could potentially result in the loss of rookery trees altogether, particularly the loss of more isolated stands, if the remaining trees were not suitable due to proximity to human disturbance. Therefore, a relatively low threshold for loss is appropriate for this CEQA analysis and a loss of 10 percent of the eucalyptus forest around Lake Merced as a result of the proposed Project would be considered significant for the purposes of this EIR.

Estimating Vegetation Response to Changes in Lake Levels

In order to determine whether Project-related impacts on biological resources could reach the thresholds defined above, vegetation responses to changes in lake levels were assessed. Building upon prior studies summarized in Section 5.14.1 (Setting), a geographic information system-based (GIS-based) vegetation map created by Nomad Ecology in 2010 was utilized as explained in the Approach to Analysis section. Using the computer program ArcGIS, ESA overlaid the 2010 vegetation data on high resolution 2010 aerial photographs and then compared the resulting imagery with existing conditions in the field. Table 5.14-4 (Lake Merced Vegetation Acreage: 2002, 2010, and 2012) presents the results of the vegetation mapping update, along with results from 2002 and 2010, for comparative purposes. See Figure 15.4-1 (Lake Merced 2012 Vegetation Types) in Section 5.14.1 (Setting) for the updated Lake Merced vegetation map.

A GIS-based analysis was then conducted to estimate vegetation response to changes in lake levels over time using the newly updated vegetation data, topography, bathymetry, slope, output from the hydrologic modeling, and 'action rules'[23] to dictate how vegetation would respond (Kennedy/Jenks 2012). For the purposes of the vegetation change analysis, the initial baseline estimates for existing vegetation acreage are those that would occur at a mean annual water surface elevation of 6 feet City Datum. This is slightly higher than the baseline 2009 water surface elevation of 5.7 feet City Datum used for the Kennedy/Jenks hydrologic modeling but was necessary in order to correspond to the topographic data, which was created at 1-foot elevation intervals. The 2012 vegetation mapping update was based on an April 2011 aerial photograph; at that time, according to historic water surface elevations data, Lake Merced water surface elevation was at about 7 feet City Datum (SFPUC 2011). The GIS-based analysis only examined vegetation at or below 13 feet City Datum, which is the existing spillway height and thus the maximum possible lake level at which vegetation changes would be expected due to changes in water level. Therefore, upland vegetation types and arroyo willow riparian scrub currently located above 13 feet City Datum, as mapped in Figure 15.14-1 (Lake Merced 2012 Vegetation Types), would remain unchanged. See Appendix J (Lake Merced Vegetation

[23] ESA biologists developed action rules for each vegetation type to estimate how vegetation would respond to increases in water surface elevation. For example, bulrush only grows in saturated soils and cannot grow if completely submerged for extended periods of time. The action rules developed for bulrush, therefore, dictate the assumption that bulrush is removed (dies) at depths greater than five feet below the water surface elevation and would establish (grow) at and up to 5 feet below the new water surface elevation.

Change Analysis Methodology), for further details on the action rules used to analyze vegetation change in response changing water surface elevations.

TABLE 5.14-4
Lake Merced Vegetation Acreage: 2002, 2010, and 2012

Vegetation Community and Cover Type	2002 (Acres; Mean Annual Water Surface Elevation: 1 foot City Datum)	2010 (Acres; Mean Annual Water Surface Elevation: 5.9 feet City Datum)	2012[(a)] (Acres)	Acreage change 2002-2012
Annual grassland	7.11	1.24	1.26	-5.85
Perennial grassland	0.49	0.01	0.01	0.48
Non-native herbaceous	17.18	12.52	11.76	-5.42
Coastal scrub	13.48	14.82	14.78	+1.30
Dune scrub	0	3.32	3.30	+3.30
Non-native scrub	0.86	0.29	0.23	-0.63
Coast live oak woodland	0.13	0.58	0.54	+0.41
Non-native forest	63.32	50.49	50.51	-12.81
Developed	188.82	197.81	198.44	+9.62
Arroyo willow riparian scrub	28.33	26.11	26.78	-1.55
Giant vetch wetland	1.13	0.29	0.25	-0.88
Rush meadow	0.71	0.20	0.32	-0.39
Swamp knotweed wetland	6.93	8.97	6.42	-0.51
Cattail wetland	0.03	0.01	0.01	-0.02
Bulrush wetland	35.14	21.1	28.16	-6.98
Open water	244.94	269.91	264.69	+19.75

Source: Nomad Ecology 2011; ESA 2012

Note:

(a) Due to construction at the Lake Merced Pump Station, the transducer has been offline since summer 2011, and, therefore, 2012 average lake levels are not available.

Two different approaches were used to estimate changes in vegetation associated with increasing and decreasing water surface elevations under the Kennedy/Jenks hydrologic models. For impacts associated with water surface elevation increases, ESA biologists worked with the San Francisco Planning Department to develop action rules for each vegetation type dictating how vegetation would respond to increasing water surface elevation (see Appendix J [Lake Merced Vegetation Change Analysis Methodology] for further details). Under rising water level conditions, there is competition and resistance to replacement of existing vegetation types by those that dominate within the inundated or saturated zone. The action rules used by the GIS-based analysis account for this by prioritizing certain vegetation types over others based on their observed capacity to invade and replace existing vegetation as water levels rise. The resulting estimates of vegetative surface area, by type, were used to estimate impacts on vegetation types due to increases in water surface elevation.

For decreasing water levels, a statistical approach was used to estimate vegetation response because the majority of land that would become available for plants to establish as water levels decrease is currently inundated and free of vegetation (except for certain wetland species). Under receding water levels, much of the land surface that becomes available for vegetation to occupy (with the exception of existing bulrush patches) would be newly exposed, unvegetated sediments of the former lake bottom. As with rising conditions, the GIS-based analysis is best able to predict vegetation types near the waterline (i.e., bulrush, knotweed, and willow), because these vegetation types have predictable distribution patterns relative to water surface elevation, as well as timing and duration of inundation. However, this analysis also acknowledges the uncertainty in the patterns of upland vegetation establishment on newly exposed terrain. Early phases of vegetation establishment are characterized by a patchy distribution of plants that lack organization into recognizable, or easily mapped, plant communities, and may be dominated by weedy and non-native species for years before native plants and communities take hold. For this reason, the GIS-based analysis does not attempt to predict changes under receding water levels for specific upland vegetation types, but instead consolidates them into a single category. For this approach, ESA analyzed the proportions of each vegetation type at each elevation contour relative to the current water surface elevation (in 2012) and applied the estimates to lower water surface elevation. This approach keeps the vegetation distribution the same for each elevation range relative to the water surface elevation, but due to differences in area driven by lake topography, the area of each vegetation type changes at each decreasing water surface elevation. For example, if the contour range of 0 to 1 foot is currently inhabited by 60 percent bulrush wetland and 40 percent knotweed wetland, those proportions would be assigned to the -1 to 0 foot contour range when analyzing a water surface decrease of 1 foot. In other words, the decreasing water vegetation GIS-based analysis assumes that the same basic mix of species and percentages of each vegetation type that exist currently (in 2012) are maintained on the newly exposed ground as water levels recede.

For both lake level increases and declines, lake-level data provide direct insight into the likelihood of impacts on riparian communities and wetlands and are represented in the hydrology model by the following summary estimates: Project performance summary (percentage of time at a given level), and lake-level continuity (number of consecutive months at a given level) (Kennedy/Jenks 2012). In other words, an examination of the percentage of time the lake levels were modeled to be at a given elevation combined with the length of time waters were modeled to stay at that elevation provided information on whether or not there could be a substantial loss of habitat over time under each modeled hydrologic scenario.

Several assumptions were made in the vegetation change analysis:

- The water surface elevations used represent the mean annual water surface elevation. Lake Merced water levels vary seasonally due to hydrologic and climatic conditions; therefore, an annual range in water surface elevation from about 1 foot above and below the mean is assumed, based on the Kennedy/Jenks (2012) hydrologic modeling, which predicts a 1.6-foot mean annual range in lake levels over the 47-year model period for the modeled existing conditions scenario. So, for example, an elevation of 6 feet City Datum, as seen in Table 15.14-4 (Lake Merced Vegetation Acreage: 2002, 2010, and 2012) actually represents a range in water surface elevation between 5 feet and 7 feet City Datum.

- The acreages given for each vegetation type at each mean annual water surface elevation in Tables 15.4-12, 5.14-13, 5.14-14, 5.14-15, and 5.14-17 assume that the water level has been at that particular elevation for a long enough period of time for the changes predicted by the action rules, which incorporate a temporal element based on the tolerances of each general vegetation type, to have taken place. For example, the action rules dictate that upland vegetation types would die if inundated or if soils are saturated for more than 14 consecutive days and that willows would die if inundated for more than 3 consecutive months in the growing season. In addition, wetlands are predicted to establish in areas inundated for more than one month's time; however, the different wetland types are expected to become fully established over periods of time ranging from several months (herbaceous wetlands) to several years (willow riparian scrub).
- The acreages estimated by the GIS-based analysis represent the vegetation that would establish if the mean water surface elevation remained at or near the same level for durations long enough for the various wetland types to establish. The analysis is consistent with the fluctuations depicted in the Lake-level Model hydrographs in that the rate of change is generally slow and water surface elevations remain relatively consistent for relatively long periods of time (Kennedy/Jenks 2012). If annual fluctuations are greater, or the rate of change is faster, than modeled, then changes in vegetation would not necessarily follow the predictions of the vegetation analysis as vegetation would continuously be reestablishing at new water surface elevations.

The impact analysis sections that follow include the results of the GIS-based analysis of vegetation and habitat changes resulting from water level changes described above, determine the Project's biological resources impacts, and determine whether the Project-related impacts would be significant according to the thresholds described above.

Areas of No Project Impact

As explained below, the Project would not result in impacts related to four of the above-listed significance criteria. These significance criteria are not discussed further in the impact analysis for the following reasons:

Direct Impacts Due to Effects on Biological Resources within Project Facility Sites

Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive or special-status plant species in local or regional plans, policies, or regulations, or by the CDFW or USFWS. Based upon biological surveys conducted at the Project facility sites, no federally or State-listed or other special-status plant species are present and none are expected to occur due to the lack of suitable habitat (Ward & Associates 2012). Therefore, neither Project construction nor operation would result in impacts on special-status plant species.

Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations, or by the CDFW or USFWS. Operation of the Project would not result in impacts on riparian habitat or sensitive natural communities because operation of the well facilities would not result in ground-disturbing activities and very limited vehicle traffic and human presence (approximately 30 minutes per day during dry years; see Chapter 3, Project Description, Section 3.8.3 [Maintenance]). Therefore, neither riparian habitat nor other sensitive natural communities would be affected.

Have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means. Operation of the Project would not result in impacts to jurisdictional wetlands or waters, because operation of the well facilities would not result in ground-disturbing activities, and no fill to wetlands or waters would occur.

Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites. Based upon biological surveys conducted at the facility sites, no resident or migratory fish or wildlife species with established resident or migratory wildlife corridors are present at the facility sites (Ward & Associates 2012). Therefore, neither Project construction nor operation would result in impacts on the movement of native special-status wildlife species or on wildlife migration corridors. Construction impacts to wildlife nursery sites (i.e., nesting by birds and roosting by bats) are evaluated in the analysis of Impact BR-2; operational impacts to wildlife nursery sites are evaluated in the analysis of Impact BR-5.

Conflict with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or State habitat conservation plan. Based on research of local, regional, and State habitat conservation plans and policies, no such plans have been adopted in the areas that would be affected by the Project. Thus, no conflict would occur between Project construction or operation and such plans.

Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance. Operation of the Project would not result in removal or trimming of trees at the facility sites, so no conflict with tree preservation policies or ordinances would occur. No other local policies or ordinances protecting biological resources have been identified; therefore, Project operations would not conflict with any such policies.

Impacts Due to Potential Changes in Water Levels at Lake Merced

Because no facilities would be constructed at Lake Merced, there are no impacts associated with construction. There would be no removal of trees, or other direct effects. Potential impacts associated with changes in water levels are evaluated in the analysis of Impacts BR-6 through BR-9.

5.14.3.3 Summary of Impacts

Table 5.14-5 (Summary of Impacts – Biological Resources) and Table 5.14-6 (Summary of Impacts on Biological Resources at Lake Merced) summarize the biological resource impacts and significance determinations of the GSR Project.

5.14.3.4 Construction Impacts and Mitigation Measures

Impact BR-1: Project construction would adversely affect candidate, sensitive, or special-status species. (Less than Significant with Mitigation)

As discussed in the Areas of No Impact section above, no special-status plants are known to occur within the study area, as identified in Section 5.14.1.4 (Special-status Plant Species). Therefore, this impact discussion focuses on special-status animal species.

No animal species listed under FESA or CESA, or which are candidates for either list, are present at any of the well facility sites, and none are expected to occur due to a lack of suitable habitat, as identified in the Section 5.14.1.5 (Special-status Animal Species). Therefore, Project construction would not result in impacts on federally listed, State-listed, or candidate wildlife species.

Nine non-listed, special-status animal species may be present in the study area; these animals are identified by the CDFW as special animals, Species of Special Concern, or, in the case of the white-tailed kite, fully protected species. Migratory birds are also protected under the MBTA and CFGC. Although the potential for their occurrence is considered low, the presence of these special-status species could not be ruled out due to the presence of suitable habitat at or adjacent to one or more of the facility sites. The evaluation of impacts for each species or group of species is provided below. The evaluation of impacts discusses sites with no impacts first, followed with less-than-significant impacts, and sites with significant impacts.

Special-status Birds and Migratory Passerines and Raptors

<u>All Sites</u>

Construction activities could remove the nesting and foraging habitat of special-status birds and other wildlife that depend on grassland, woodland, and riparian habitat through direct removal of habitat, or could result in disruption of breeding and foraging habitat due to construction noise and activities. Project construction could result in the removal of large mature trees in developed and ruderal areas that provide important nesting habitat for nesting birds, raptors, and bats. Suitable nesting habitat for migratory birds is present within the construction areas of Sites 1, 3, 4, 7, 9, 11, 12, 13, 15, 17 (Alternate), and 19 (Alternate). Marginally suitable habitat for migratory birds is present adjacent to Sites 2, 5, 6, 8, 10, 14, 16, 18 (Alternate), and the Westlake Pump Station.

The facility sites have large trees and shrubs either within or near the construction area of the facility sites. The trees and shrubs could provide nesting habitat for special-status bird species including white-tailed kite, oak titmouse, loggerhead shrike, Allen's hummingbird, and California thrasher, as well as migratory raptors and passerine bird species. All facility sites have trees and shrubs in close proximity to the site that could be used for nesting by special-status and other migratory birds. Construction activities would result in tree removal or trimming of nearby trees at some sites which would result in impacts to special-status and migratory birds if present in the trees and shrubs. Construction activities could also disturb nesting and breeding birds in trees and shrubs near the facility sites. Potential impacts on special-status and migratory birds that could result from Project construction activities include the destruction of eggs or occupied nests, mortality of young, and the abandonment of nests with eggs or young birds prior to fledging. Such potential construction-related impacts on special-status and migratory birds would be *significant*.

However, implementation of Mitigation Measure M-BR-1a (Protection Measures during Construction for Special-status Birds and Migratory Passerines and Raptors) would mitigate these potential impacts on special-status and migratory birds to *less-than-significant* levels by requiring pre-construction surveys by a qualified biologist to determine whether special-status or migratory bird nests are present at or near the well facility sites and implementing related protection measures.

> ***Mitigation Measure M-BR-1a: Protection Measures during Construction for Special-status Birds and Migratory Passerines and Raptors (All Sites)***
> The SFPUC shall conduct tree and shrub removal at the facility sites during non-breeding season (generally August 31 through February 28) for special status, migratory birds and raptors, to the extent feasible.

If construction activities must occur during the breeding season for special-status birds (March 1 to August 30), the SFPUC shall retain a qualified wildlife biologist who is experienced in identifying birds and their habitat to conduct a pre-construction survey for nesting special-status birds and migratory passerines and raptors. The preconstruction surveys must be conducted within two weeks prior to the initiation of tree removals or pruning, grading, grubbing, structure demolition, or other construction activities scheduled during the breeding season (March 1 to August 30). If the biologist detects no active nesting or breeding activity by special-status or migratory birds or raptors, then work may proceed without restrictions. To the extent allowed by access, all active passerine nests identified within 100 feet and all active raptor nests identified within 250 feet of the limits of work shall be mapped.

If migratory bird and/or active raptor nests are identified within 250 feet of a facility site or if an active passerine nest is identified within 100 feet of a facility site, a qualified biologist shall determine whether or not construction activities might impact the active nest or disrupt reproductive behavior. If it is determined that construction would not affect an active nest or disrupt breeding behavior, construction may proceed without any restriction.

If the qualified biologist determines that construction activities would likely disrupt raptor breeding or passerine nesting activities, then the SFPUC shall establish a no-disturbance buffer around the nesting location to avoid disturbance or destruction of the nest site until after the breeding season or after a wildlife biologist determines that the young have fledged (usually late June through mid-July). The extent of these buffers would be determined by a wildlife biologist in consultation with CDFW and would depend on the species' sensitivity to disturbance (which can vary among species); the level of noise or construction disturbance; line of sight between the nest and the disturbance; ambient levels of noise and other disturbances; and consideration of other topographical or artificial barriers. The wildlife biologist shall analyze and use these factors to assist the CDFW in making an appropriate decision on buffer distances.

Impact Conclusion: Less than Significant with Mitigation

Special-status Bats

The evaluation of impacts that follows discusses sites with no impacts first, followed by those with significant impacts.

<u>Sites 2, 5, 6, 8, 9, 13, 14, 17 (Alternate), 18 (Alternate), 19 (Alternate), and the Westlake Pump Station</u>

No trees suitable for bat roosting occur on or adjacent to these sites. Although the proposed Project could include demolition of an existing well and above-ground tank at Site 14, the features do not provide potential habitat for special-status bats. These sites do not support the habitat characteristics necessary for roosting; therefore, no construction-related impacts on special-status bats would occur at these sites.

Impact Conclusion: No Impact

Sites 1, 3, 4, 7, 10, 11, 12, 15, and 16

Significant impacts on special-status bat species could result from well facility construction activities that require tree removals or trimming of trees that provide suitable roosting habitat for special-status bat species or that are occupied by roosting bats. The demolition of the restroom facility (in addition to tree removal) at Site 1, where bats may roost, could also result in significant impacts on special-status bat species. The pallid bat, western red bat, and hoary bat could roost in trees on or near these sites. Disturbance during the maternity roosting season could potentially result in roost abandonment and mortality of young. For instance, bats could abandon their young if impacts were to occur during seasonal periods of breeding activity (about February 15 through April 15 and August 15 through October 30). Therefore, Project construction could result in both permanent and temporary loss of suitable or occupied habitat for, as well as mortality of, special-status bat species, which would be a *significant* impact.

However, implementation of Mitigation Measure M-BR-1b (Protection Measures for Special-status Bats during Tree Removal or Trimming) and Mitigation Measure M-BR-1c (Protection Measures during Structure Demolition for Special-status Bats) would reduce impacts on special-status bat species to *less-than-significant* levels by requiring pre-construction surveys and the avoidance of disturbance to roosting bats.

Mitigation Measure M-BR-1b: Protection Measures for Special-status Bats during Tree Removal or Trimming (Sites 1, 3, 4, 7, 10, 11, 12, 15, and 16)

The SFPUC will ensure that, prior to the removal of large trees scheduled during seasonal periods of bat activity (February 15 through April 15 and August 15 through October 30), a qualified bat biologist conducts a bat habitat assessment to determine the presence of suitable bat roosting habitat. No more than 30 days before removal of any large tree or snag, a biologist familiar with identification of bats and signs of bats will conduct a pre-construction survey for signs of bat activity. If tree removal or trimming is postponed or interrupted for more than 30 days from the date of the initial bat survey, the biologist will repeat the pre-construction survey.

If a tree provides potentially suitable roosting habitat, but bats are not present, the SFPUC shall exclude bats by temporarily sealing cavities, pruning limbs, or removing the entire tree, in consultation with the qualified bat biologist. Trees and snags with cavities or loose bark that exhibit evidence of use by bats shall be scheduled for bat exclusion and/or eviction, conducted during appropriate seasons (i.e., February 15 through April 15 and August 15 through October 30) and supervised by the biologist.

If the biologist determines or presumes bats are present, the biologist shall exclude the bats from suitable tree cavities by installing one-way exclusion devices. After the bats vacate the cavities, the biologist shall plug the cavities or remove the limbs. The construction contractor shall only remove trees after the biologist verifies that the exclusion methods have successfully prevented bats from returning, usually in seven to 10 days. To avoid impacts on non-volant (i.e., non-flying) bats, the biologist shall only conduct bat exclusion and eviction from February 15 through April 15 and from August 15 through October 30. After construction activities are complete, the biologist will remove the exclusion devices.

Mitigation Measure M-BR-1c: Protection Measures during Structure Demolition for Special-status Bats (Site 1)

Not more than two weeks prior to building demolition at Site 1, a qualified biologist (i.e., one familiar with the identification of bats and signs of bats) shall survey the building for the presence of roosting bats or evidence of bats. If no roosting bats or evidence of bats are found in the structure, demolition may proceed. If the biologist determines or presumes bats are present, the biologist shall exclude the bats from suitable spaces by installing one-way exclusion devices. After the bats vacate the space, the biologist shall close off the space to prevent recolonization. The construction contractor shall only demolish the building after the biologist verifies that the exclusion methods have successfully prevented bats from returning, usually in seven to 10 days. To avoid impacts on non-volant (i.e., non-flying) bats, the biologist shall only conduct bat exclusion and eviction from February 15 through April 15 and from August 15 through October 30.

Impact Conclusion: Less than Significant with Mitigation

Overwintering Monarch Butterfly Habitat

The evaluation of impacts that follows discusses sites with no impacts first, followed by those with significant impacts.

<u>Sites 2, 4, 5, 6, 8, 9, 11, 13, 14, 15, 16, 17 (Alternate), 18 (Alternate), 19 (Alternate), and the Westlake Pump Station</u>

No dense stands of eucalyptus, Monterey pine, or Monterey cypress trees occur at or adjacent to these sites. Therefore, these sites do not support the habitat suitable for overwintering by monarch butterflies. As a result, no construction-related impacts on roosting monarch butterflies would occur at these sites.

Impact Conclusion: No Impact

<u>Sites 1, 3, 7, 10, and 12</u>

Although unlikely, given that overwintering of monarch butterflies at these locations has not been reported (CDFG 2011f), the dense stands of large eucalyptus, Monterey pine, and Monterey cypress trees at these sites could nevertheless support overwintering monarch butterflies. This species' overwintering sites are considered to have special-status by the CDFG (CDFG 2011c). The removal or pruning of trees actively used by overwintering monarch butterflies during the winter roosting period would therefore constitute a *significant* impact on a special-status species.

However, implementation of Mitigation Measure M-BR-1d (Monarch Butterfly Protection Measures) would reduce this potential impact to *less-than-significant* levels by requiring an inspection by a qualified biologist prior to the limbing or felling of trees or the initiation of construction activities on these sites, whichever comes first; and by delaying construction at a particular site if overwintering congregations of monarch butterflies are identified on site or nearby.

Mitigation Measure M-BR-1d: Monarch Butterfly Protection Measures (Sites 1, 3, 7, 10, and 12)

The SFPUC will ensure that, two weeks prior to removing or pruning large eucalyptus, Monterey pine or Monterey cypress trees that occur in a dense stand, a qualified biologist conduct surveys for monarch butterflies if the trees are to be removed or limbed between October 15 and March 1. If no congregations of monarch butterflies are present within the contiguous stand of dense trees, work may proceed without restriction.

A pre-construction inspection is not needed for construction activities occurring between March 2 and October 14.

If overwintering congregations of monarch butterflies are identified within the tree stand, work may not proceed until the butterflies have left the roosting site. No limbing or tree cutting shall occur in a contiguous stand of trees occupied by monarch butterflies. A qualified biologist shall determine when the butterflies have left and when work in the area may proceed.

Impact Conclusion: Less than Significant with Mitigation

Impact BR-2: Project construction could adversely affect riparian habitat or other sensitive natural communities. (Less than Significant with Mitigation)

The evaluation of impacts that follows discusses sites with no impacts first, followed by those with significant impacts.

<u>Sites 2 through 16, 17 (Alternate), 18 (Alternate), 19 (Alternate), and the Westlake Pump Station</u>

No riparian habitat or other sensitive natural communities are present within the construction area boundaries or in areas adjacent to any of these facility sites. Project construction at these locations therefore would not result in impacts on riparian habitat or other sensitive natural communities; *no impact* would occur.

An isolated patch of willows, classified as ruderal (weedy or disturbed) habitat, is present inside the construction area boundary of Site 18 (Alternate). Ruderal habitat is not considered a sensitive natural community.

Isolated patches of Central Coast riparian scrub habitat not associated with a surface tributary are present near the construction areas for Sites 6 and 17 (Alternate); the habitat in these areas is assumed to be supported by groundwater. Also, an unnamed drainage channel supports a stand of Central Coast riparian scrub near Site 11. The location of the Central Coast riparian scrub near Sites 6, 11, and 17 (Alternate) is shown on Figures 5.14-3 through 5.14-6. Riparian habitat at Site 6 is located approximately 50 feet southwest of the construction area. Riparian habitat at Site 11 is located approximately 15 feet from the northwest corner of the construction area. The willow stand in this area is approximately 5,060 square feet. The habitat near Site 17 (Alternate) is located adjacent to the western edge of the construction area boundary on the north side of Collins Avenue. No Central Coast riparian scrub habitat would be directly impacted at Sites 6, 11, or 17 (Alternate) as the habitat is located outside of the construction area. In addition, the riparian habitat is located at a higher elevation than the construction areas at Sites 6, 11, and 17 (Alternate), so stormwater runoff from the construction site would not affect the habitat. As a result, *no impact* on riparian habitat or other sensitive natural habitat would occur at these facility sites.

Impact Conclusion: No Impact

<u>Site 1</u>

An isolated patch of Central Coast riparian scrub habitat not associated with a surface tributary is present adjacent to the construction area at Site 1. The habitat in this area is assumed to be supported by groundwater. No Central Coast riparian scrub habitat would be directly impacted at Site 1, as the habitat is located out of the construction area boundary. The 305 square feet of riparian habitat adjacent to Site 1 is located immediately adjacent to the northwest edge of the construction area boundary. Although construction at this site would not result in the loss of Central Coast riparian scrub habitat, construction near the habitat could result in stormwater runoff which could carry sediment into the area and adversely impact the habitat. If so, such impacts on Central Coast riparian scrub habitat from excessive sedimentation would be *significant*.

However, implementation of Mitigation Measure M-HY-1 (Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan) and M-BR-2 (Avoid Disturbance to Riparian Habitat) would reduce the potential impacts on riparian habitat at Site 1 to *less-than-significant* levels by requiring the installation of temporary fencing to demarcate the boundary for construction activities at this site and by protecting the area from construction-related runoff and sedimentation.

Mitigation Measure M-HY-1: Develop and Implement a Storm Water Pollution Prevention Plan (SWPPP) or an Erosion and Sediment Control Plan (All Sites)
(See Impact HY-1 in Section 5.16, Hydrology and Water Quality for a description)

Mitigation Measure M-BR-2: Avoid Disturbance to Riparian Habitat (Site 1)
The SFPUC shall require its construction contractor to avoid the riparian habitat at Site 1. Prior to any ground disturbing activity, a qualified biologist shall map the location of the Central Coast riparian scrub habitat, and the construction contractor shall install temporary fencing to protect the habitat for the duration of construction.

Impact Conclusion: Less than Significant with Mitigation

Impact BR-3: The Project would impact jurisdictional wetlands or waters of the United States (Less than Significant with Mitigation).

The evaluation of impacts that follows discusses sites with no impacts first, followed by those with significant impacts.

<u>Sites 1, 2, 3, 4, 5, 6, 7, 10, 12, 13, 14, 15, 16, 17 (Alternate), 18 (Alternate), 19 (Alternate), and the Westlake Pump Station</u>

No federally regulated wetlands or surface waters of the United States/waters of the State are present within the construction area boundaries of these facility sites. Project construction at these locations would therefore result in *no impact* on wetlands or waters of the United States/waters of the State.

Impact Conclusion: No Impact

<u>Sites 8, 9, and 11</u>

An underground culvert crosses beneath a portion of the Site 8 construction area. Water in the culvert is a tributary to Colma Creek, and therefore would qualify as a jurisdictional water of the United States and the State. However, no direct impacts to the culvert or the tributary would occur as a result of Project construction.

Site 9 would be located approximately 25 feet from channelized sections of the Colma Creek Diversion Channel and the San Mateo County Flood Control Channel as illustrated on Figure 5.14-7 (Site 9, Treasure Island Trailer Court, Jurisdictional Waters). Stormwater runoff from this site could drain to either channel. Site 11 would be located approximately 200 feet from the Colma Creek Diversion Channel, and the construction area at the northwest edge of the site

would be within approximately 15 feet of an unnamed drainage channel that supports a stand of Central Coast riparian scrub. The Central Coast riparian scrub and jurisdictional waters at Site 11 are shown on Figure 5.14-4 (Site 11 Pipeline and Access Road, South San Francisco Main Area, Central Coast Riparian Scrub and Jurisdictional Waters). No direct impacts on the Colma Creek Diversion Channel, the San Mateo County Flood Control Channel, or the unnamed channel northwest of Site 11 would occur during construction, because these jurisdictional waters are not located within the construction area at Site 9 or Site 11.

Stormwater leaving the Site 11 construction area would not affect the unnamed drainage channel northwest of the site, because the facility is at a lower elevation than the channel. However, stormwater runoff leaving the construction area at Sites 8 and 9 could carry sediment or other contaminants into the on-site culvert at Site 8 or the Colma Creek Diversion Channel or the San Mateo County Flood Control Channel at Sites 9 and 11. Uncontrolled stormwater runoff could result in discharge and sedimentation to jurisdictional waters, which would be a *significant impact.* However, implementation of Mitigation Measure M-HY-1 (Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan) would reduce impacts to *less-than-significant* levels by protecting the area from construction-related runoff and sedimentation.

> ***Mitigation Measure M-HY-1: Develop and Implement a Storm Water Pollution Prevention Plan (SWPPP) or an Erosion and Sediment Control Plan (All Sites)***
> (See Impact HY-1 in Section 5.16, Hydrology and Water Quality for a description)

Impact Conclusion: Less than Significant with Mitigation

Impact BR-4: Project construction would conflict with local tree preservation ordinances. (Less than Significant with Mitigation)

As identified in the regulatory framework discussion in Section 5.14.2.3 (Local), the relevant policies and ordinances protecting trees in the study area are the San Mateo County Significant and Heritage Tree Ordinances (San Mateo County Ordinance Code: Part III, Division VIII. (The Significant Tree Ordinance of San Mateo County) and Ordinance Number 2427 (Regulation of the Removal and Trimming of Heritage Trees on Public and Private Property), the City of Daly City Municipal Code (Daly City Municipal Code, Title 12: Chapter 12.40. Chapter 12.40, Urban Forestry), the Town of Colma Municipal Code (Town of Colma Municipal Code: Subchapter Six. Subchapter Six, Tree Cutting and Removal), the City of South San Francisco Municipal Code (City of South San Francisco Municipal Code: Chapter 13.30. Chapter 13.30, Tree Preservation), and City of San Bruno Municipal Code (City of San Bruno Municipal Code: Chapters 8.24 and 8.25. Chapter 8.25, Heritage Tree Ordinance). The criteria for tree protection in each of the local tree preservation ordinances were used to identify protected trees in the study area, assess the impact of the proposed Project on the trees at each facility site, and develop mitigations to address impacts.

The evaluation of impacts that follows discusses sites with no impacts first, followed by those with significant impacts.

Sites 1, 2, 5, 6, 8, 16, 19 (Alternate), and the Westlake Pump Station

Project implementation at the above-listed sites would not result in impacts on trees regulated under local ordinances because either no such trees are present on these sites or, at the Westlake Pump Station, they would be avoided during construction activities. The applicable local jurisdiction for each of these sites is as follows: Sites 1, 5, and 6 would be located in Daly City; Site 2 would be located in unincorporated San Mateo County (Broadmoor); Site 8 would be located in Colma; Site 16 would be located in Millbrae; and Site 19 (Alternate) in South San Francisco. As a result, development of these sites would not conflict with local ordinances aimed at protecting trees. Therefore, *no impact* would occur at these sites relative to this criterion.

Impact Conclusion: No Impact

Sites 3, 4, 7, 9, 10, 11, 12, 13, 14, 15, 17 (Alternate), and 18 (Alternate)

A total of 59 trees within the proposed construction areas that would qualify for protection under local tree protection ordinances could be removed, as shown in Tables 5.14-7 through 5.14-10, if all these sites were developed. An additional 53 protected trees located in the study area surrounding these sites (i.e., those that would be adjacent to the construction areas or along pipeline routes) could be trimmed to accommodate construction.

Sites 3 and 4 would be located in the Broadmoor community of unincorporated San Mateo County. No significant or heritage trees are present within the proposed construction area at Site 3; however, two protected Monterey pines, were identified adjacent to the construction boundary. These trees may be trimmed during construction, and tree trimming of protected trees is regulated in the local preservation ordinances. Three protected Monterey cypress trees are located within the construction area for Site 4 and would be removed during construction. In addition, two protected Monterey cypress trees would be trimmed during construction at this site. Protected trees to be removed or trimmed are identified in Table 5.14-7 (San Mateo County Protected Trees).

TABLE 5.14-7
San Mateo County Protected Trees

Site	Protected Trees *in* the Construction Area Boundary	Tree Species	Protected Trees *Adjacent to* the Construction Boundary	Tree Species
Site 3	0	N/A	2[(a)]	Monterey pine
Site 4	3	Monterey cypress	2[(a)]	Monterey cypress

Note:

(a) Trees do not meet the County's definition of a Heritage Tree (San Mateo County 1977)

Site 7, located in the Town of Colma, has 25 protected trees in the proposed construction area boundary and an additional 13 protected trees adjacent to the boundary and subject to trimming or pruning to accommodate construction activities in the area. Trees within the construction area boundary would be removed during construction. Protected trees to be removed or trimmed are identified in Table 5.14-8 (Town of Colma Protected Trees).

TABLE 5.14-8
Town of Colma Protected Trees

Site	Protected Trees *in* the Construction Area Boundary	Tree Species	Protected Trees *Adjacent to* the Construction Boundary	Tree Species
Site 7	1	Monterey pine	13	Tasmanian blue gum
	19	Tasmanian blue gum		
	1	Scarlet flowing gum		
	1	Horsetail casuarina		
	1	Peruvian pepper		
	1	Myoporum		
	1	Spruce		
Site 17 (Alternate)	0	NA	2	Monterey cypress

In South San Francisco, at Site 9, one large Monterey pine that would be removed during construction qualifies as a locally protected tree. No protected trees are present in the construction area for Sites 10, 11, or 13. However, several protected trees are located adjacent to the boundaries of Sites 10, 11, and 13 which may require trimming or pruning to accommodate construction activities in the area, as shown below. The South San Francisco Tree Preservation Ordinance regulates pruning or altering protected trees in any way. At Site 12, 28 protected trees may be removed and four protected trees trimmed. At Site 18 (Alternate), one protected tree may need to be removed. Protected trees to be removed or trimmed are identified in Table 5.14-9 (South San Francisco Protected Trees).

TABLE 5.14-9
South San Francisco Protected Trees

Site	Protected Trees *in* the Construction Area Boundary	Tree Species	Protected Trees *Adjacent to* the Construction Boundary	Tree Species
Site 9	1	Monterey pine	0	NA
Site 10[a]	0	NA	1	Monterey pine
			2	Monterey cypress
Site 11	0	NA	1	Lombardy poplar
			3	Torrey pine
			2	Tasmanian blue gum
Site 12	5	Monterey cypress	4	Monterey cypress
	10	Monterey pine		
	9	Dwarf blue gum		
	3	Tasmanian blue gum		
	1	Aleppo pine		
Site 13[b]	0	NA	5	Gum tree
			6	Italian stone pine
			1	Tasmanian blue gum
Site 18 (Alternate)	1	Ornamental plum	0	NA

Notes:

(a) Trees adjacent the Site 10 construction area boundary would not require trimming, but are listed in the table as trees adjacent to the construction area.

(b) Trees adjacent to Site 13 would not require trimming, but are listed in the table as trees adjacent to the construction area boundary. The trees are street trees along Huntington Avenue.

Site 15 would be located at the Golden Gate National Cemetery in San Bruno. The City's municipal code restricts removal or alteration of any tree without a permit. No protected tree would need to be removed at Site 14 (also at the Golden Gate National Cemetery in San Bruno). Site 15 has one elm tree in the construction area boundary that meets the definition of a protected tree and that would need to be removed. In addition, the pipelines for Sites 14 and 15 and removal of existing well building may require trimming of 22 protected trees along Sneath Lane and two trees within the cemetery during construction. Although the pipelines for both sites would be installed along Sneath Lane, for purposes of this analysis, these tree impacts are attributed to Site 15 only. Protected trees to be removed or trimmed are identified in Table 5.14-10 (San Bruno Protected Trees).

TABLE 5.14-10
San Bruno Protected Trees

Site	Protected Trees *in* the Construction Area Boundary	Tree Species	Protected Trees *Adjacent to* the Construction Boundary	Tree Species
Site 14	0	n/a	1	Olive
			1	Myoporum
Site 15	1	Elm	4	Monterey pine
			3	myoporum
			2	Spanish bayonette
			3	Tasmanian blue gum
			2	Elm
			3	Aleppo pine
			5	Canary Island pine

Tree removal or tree pruning that is inconsistent with the San Mateo County tree preservation ordinances, the City of Daly City Municipal Code, the Town of Colma Municipal Code, the City of South San Francisco Municipal Code, or the City of San Bruno Municipal Code would be a *significant* impact on a locally protected biological resource. However, these impacts would be reduced to *less-than-significant* levels by implementation of Mitigation Measure M-BR-4a (Minimize Impacts on Protected Trees to Avoid Tree Loss) and Mitigation and Measure M-BR-4b (Protected Tree Replacement), which would fulfill the intent of the local tree preservation ordinances and codes by minimizing impacts on protected trees and by requiring replacement trees for any protected trees that are removed, in substantial accordance with local jurisdiction requirements. These measures would therefore resolve the conflict with the local tree protection ordinances.

Mitigation Measure M-BR-4a: Identify Protected Trees (Sites 3, 4, 7, 10, 11, 12, 13, 14, 15, and 17 [Alternate])

The SFPUC shall identify trees to be protected during construction activities. These trees shall be marked on construction plans and protected during construction activities according to requirements presented in Mitigation Measure M-AE-1b (see Section 5.3, Aesthetics for a description of the tree protection measures). For each protected tree that is removed as part of construction activities, replacement trees shall be planted according to local requirements, as stated in Mitigation Measure M-BR-4b (Protected Tree Replacement).

M-AE-1b: Tree Protection Measures (Sites 3, 4, 7, 10, 11, 12, 13, 14, 15, and 17 [Alternate])
(See Section 5.3, Aesthetics for a description)

Mitigation Measure M-BR-4b: Protected Tree Replacement (Sites 4, 7, 9, 12, 15, and 18 [Alternate])
The SFPUC shall replace protected trees in accordance with the requirements specified in this mitigation measure and at the ratios specified in this measure for the jurisdiction where the trees to be removed are located. Protected non-native trees removed shall be replaced with native tree species determined suitable for the site by a qualified arborist, horticulturist, landscape architect, or biologist.

Tree Replacement Requirements Common to All Jurisdictions

- Trees shall be replaced within the first year after completion of construction, or as soon as possible in areas where construction has been completed, during a favorable time period for replanting, as determined by a qualified arborist, horticulturist, or landscape architect.
- Selection of replacement sites and installation of replacement plantings shall be supervised by a qualified arborist, horticulturist, landscape architect, or landscape contractor. Irrigation of trees during the initial establishment period (generally for two to four growing seasons) shall be provided as deemed necessary by a qualified arborist, horticulturist, landscape architect, or landscape contractor.
- Trees shall be planted at or in close proximity to removal sites, in locations suitable for the replacement species. The specialist shall work with the SFPUC to determine appropriate nearby off-site locations that are within the same jurisdiction from which the trees are removed if replanting within the well facility sites is precluded.
- A qualified arborist, horticulturist, landscape architect, or landscape contractor shall monitor newly planted trees at least twice a year for five years. Each year, any trees that do not survive shall be replaced and monitored at least twice a year for five years thereafter.

San Mateo County Tree Ordinance Replacement Requirements

- For each significant/heritage tree removed during construction or lost due to construction-related impacts, a replacement tree shall be planted. Native trees shall be replaced with the same species, and nonnative trees shall be replaced with a native tree species determined suitable for the site by a qualified arborist, horticulturalist, or landscape architect.

- Each protected tree removed shall be replaced at a 1:1 ratio of a native variety that has the potential to reach a size similar to that of the removed trees.

Town of Colma Tree Replacement Requirements

- Each protected tree removed shall be replaced at a 1:1 ratio. Native trees shall be replaced with the same species, and nonnative trees shall be replaced with a native tree species determined suitable for the site by a qualified arborist, horticulturalist, or landscape architect.

City of South San Francisco Tree Replacement Requirements

- Each protected tree removed shall be replaced with three 24-inch-box sized or two 36-inch-box sized landscape trees.

City of San Bruno Tree Replacement Requirements

- Tree replacement shall be a minimum of either two 24-inch box size trees, or one 36-inch box size tree, for each heritage tree removed.

Impact Conclusion: Less than Significant with Mitigation

5.14.3.5 Operational Impacts and Mitigation Measures

Impact BR-5: Project operations could adversely affect candidate or sensitive special-status species. (Less than Significant with Mitigation)

The evaluation of impacts that follows discusses sites with no impacts first, followed by less-than-significant impacts, and significant impacts.

Special-Status Birds and Migratory Passerines and Raptors

<u>Sites 2, 3, 4, 5, 6, 7 (Consolidated Treatment at Site 6), 8, 9, 10, 14, and 19 (Alternate)</u>

Operation and maintenance activities would not result in a loss of habitat for special-status or other migratory birds and would not result in additional loss of suitable nesting trees. Well facilities at some sites (2, 3, 4, Site 7 [Consolidated Treatment at Site 6], Site 14, and Site 19 [Alternate]) would have a submersible pump. Submersible pumps would be installed underground and would, therefore, not result in measurable noise above ground (see Chapter 5.7, Noise and Vibration, Impact NO-5). Maintenance would include well exercising that would occur either weekly or monthly for one hour per week or for a single, four-hour period monthly. (see Chapter 5.7 Noise and Vibration, Impact NO-5, and Chapter 3, Project Description, Section 3.8.3 [Maintenance]). Other operational noise would be limited to supply trucks for operational and maintenance purposes which would slightly increase noise from local vehicle trips, and therefore there would be *no impacts* on sensitive biological resources relative to noise at the submersible pump sites. Sites 5, 6, 8, 9, and 10 would not be located at or near areas that support habitat for special-status birds or migratory passerines or raptors, and therefore these sites would have *no impacts* on such biological resources relative to operational noise.

Impact Conclusion: No Impact

<u>Sites 11, 13, 15, 16, and 17 (Alternate)</u>

Operation and maintenance activities would not result in a loss of habitat for special-status or other migratory birds and would not result in additional loss of suitable nesting trees. Operational noise from the well facilities would result primarily from running the well pump. Supply trucks for operation and maintenance purposes would also slightly increase the vehicle trips and noise generation at these sites (see Section 5.7, Noise and Vibration). Maintenance includes well exercising that would occur either weekly or monthly for one hour per week or for a single, four-hour period monthly (see Chapter 5.7, Noise and Vibration, Impact NO-5 and Chapter 3, Project Description, Section 3.8.3 [Maintenance]).

The proposed operational noise levels at these sites would be within the range of the existing ambient noise levels at the well facility sites or below 50 dBA **(**see Section 5.7, Noise and Vibration, Impact NO-5). Because of this, and also the limited amount of vehicle trips, operation and maintenance of the well facilities would not result in new or increased impacts on nesting special-status or other, migratory birds. Noise associated with operation and maintenance would not likely prevent any birds from nesting in the trees near these sites, given that this potential change in ambient conditions would not be substantial, as compared to existing conditions. Potential operational impacts on special-status and migratory bird species would therefore be *less than significant*.

Impact Conclusion: Less than Significant

<u>Sites 1, 7 (On-site Treatment), 12, 18 (Alternate), and the Westlake Pump Station</u>

As identified Section 5.7, Noise and Vibration, noise levels during well operation at Sites 1, 7 (On-Site Treatment), 12, 18 (Alternate), and the Westlake Pump Station would exceed the ambient noise or exceed 50 dBA. These sites would also be located near habitat for special-status birds that could be impacted by the operational noise expected at these sites, given that this noise could interfere with nesting. Therefore, this potential impact on sensitive biological resources would be *significant*.

However, implementation of Mitigation Measure M-NO-5 (Operational Noise Control Measures) would also have the effect of reducing this potential impact on sensitive biological resources to *less–than-significant* levels by requiring that the final design of pump stations incorporate features to reduce noise levels below (by at least 1 dBA) the most restrictive threshold (the local noise standard or the sleep interference threshold). The most restrictive threshold used by the noise analysis in Section 5.7, Noise and Vibration, is the sleep interference threshold, which is 50 dBA, as measured at the exterior of the building of the closest noise-sensitive receptor. Reducing operational noise below 50 dBA to address identified operational noise impacts would also have the effect of reducing this potential impact on special-status species utilizing the habitat adjacent to these well facility sites.

Upgrades to the Westlake Pump Station would be necessary to serve the well facilities at Sites 2, 3, and 4. The size and exact location of proposed new equipment at the Westlake Pump Station is not known at this time. Therefore, this analysis conservatively assumes that the impact of operational noise from the Westlake Pump Station on the special-status species habitat adjacent to the pump station would be potentially *significant*. However, implementation of Mitigation Measure M-NO-5 (Operational Noise Control Measures) would also have the effect of reducing this potential impact on sensitive biological resources to *less-than-significant* levels by requiring noise reduction measures at the site.

> ***Measure M-NO-5: Operational Noise Control Measures (Sites 1, 5 [On-site Treatment], 7 [On-site Treatment], 9, 12, 18 [Alternate], and the Westlake Pump Station)***
> (See Impact NO-5 in Chapter 5.7, Noise and Vibration for a description)

Impact Conclusion: Less than Significant with Mitigation

Special-Status Bats or Bats of Special Concern

<u>Sites 2, 5, 6, 8, 9, 13, 14, 17 (Alternate), 18 (Alternate), and 19 (Alternate)</u>

No trees suitable for bat roosting occur on or near these sites. As a result, these sites do not support the habitat characteristics necessary for bat roosting. Therefore, no operation-related impacts on special-status bats would occur.

Impact Conclusion: No Impact

<u>Sites 1, 3, 4, 7, 10, 11, 12, 15, 16, and the Westlake Pump Station</u>

Operation and maintenance activities at these sites would not result in a loss of roosting habitat for special-status bats, as such activities would not result in an additional loss of trees suitable for roosting. Maintenance includes well exercising that would occur either weekly or monthly for one hour per week or for a single, four-hour period monthly. Operators may fine-tune the exercise schedule according to the characteristics of individual wells (see Chapter 3, Project Description, Section 3.8.3 [Maintenance]). Maintenance site visits, supply trucks for operation and maintenance purposes, and operation of the well pumps would slightly increase the vehicle trips and noise generation at each site. However, this would not likely result in a substantial increase in ambient noise levels that could affect special-status bats given that operational noise levels at these sites would be within the range of the existing ambient noise levels (see Section 5.7, Noise and Vibration, Impact NO-5). Therefore, operational noise levels would not prevent bats from utilizing habitat near these sites. As a result, potential impacts on special-status bats at these sites would be *less than significant*.

Impact Conclusion: Less than Significant

Overwintering Monarch Butterfly Habitat

Sites 2, 4, 5, 6, 8, 9, 11, 13, 14, 15, 16, 17 (Alternate), 18 (Alternate), 19 (Alternate), and the Westlake Pump Station

Project operations would not impact monarch butterfly, because no dense stands of eucalyptus, Monterey pine or Monterey cypress trees occur at or adjacent to these sites, and potential winter roosting habitat would therefore not be affected during operations and maintenance activities.

Impact Conclusion: No Impact

Sites 1, 3, 7, 10, and 12

Although unlikely, given that overwintering of monarch butterflies at these locations has not been reported (CDFG 2011f), the dense stands of large eucalyptus, Monterey pine, and Monterey cypress trees at these sites could nevertheless support overwintering monarch butterflies. Project operations would have *less-than-significant* impacts on monarch butterflies because no additional trees would be removed during Project operations and potential winter roosting habitat would therefore not be affected during operations and maintenance activities. Maintenance includes well exercising that would occur either weekly or monthly for one hour per week or for a single, four-hour period monthly. Operators may fine-tune the exercise schedule according to the characteristics of individual wells (see Chapter 3, Project Description, Section 3.8.3 [Maintenance]). Maintenance site visits, supply trucks for operation and maintenance purposes, and operation of the well pump would slightly increase the vehicle trips and noise generation at each site, but would not likely result in a substantial increase in ambient noise levels (see Section 5.7, Noise and Vibration, Impact NO-5) or other disturbances likely to affect overwintering monarch butterflies, given that such activities would not occur in the midst of currently utilized winter roosts.

Impact Conclusion: Less than Significant

5.14.3.6 Impacts of Lake Level Changes on Biological Resources at Lake Merced and Mitigation Measures

The following description of modeled existing conditions and predicted impacts of the proposed Project present the data used for the subsequent impact analyses in Impacts BR-6 through BR-9, which address the potential that the project could change water levels at Lake Merced, with resulting effects on biological resources at the lake.

Modeled Existing Conditions

The modeled existing conditions represent a simulated estimation of hydrologic conditions that are expected to occur over the 47-year modeling period without construction and operation of the GSR Project, based upon historic hydrologic conditions. Under the modeled existing conditions, simulated water levels clearly respond to modeled climatic variations, including wet, normal, and dry precipitation years and the same hydrologic sequencing is used for each model scenario. See Section 5.1 Overview, Section 5.1.6 (Groundwater Modeling Overview), for further details on the hydrologic modeling. The modeled mean annual range between maximum and minimum lake levels would be 1.6 feet City Datum (Kennedy/Jenks 2012). Maximum lake levels over the model period are predicted at 12.4 feet City Datum, or 6.7 feet above the average baseline water surface elevation of 5.7 feet City Datum. Minimum water surface elevations could reach as low as -0.8 feet City Datum, or 6.5 feet below the baseline average water surface elevation of 5.7 feet City Datum (see Figures 5.16-11 [Simulated Lake Merced Level Changes] and 5.16-12 [Simulated Lake Merced Levels Relative to Modeled Existing Conditions]) (Kennedy/Jenks 2012).

While the lake-level models are based on historical records, the various hydrologic conditions would not necessarily happen in the same sequence as modeled, although it is assumed for the purposes of the lake level model and for this analysis that they would occur at some point during the modeled time period. The modeled existing conditions (see Figures 5.16-11 and 5.16-12) show an initial sharp increase in lake levels from 5.7 feet City Datum to over 12 feet City Datum, responding to a period of above-average precipitation in model years 1 to 4. Years 4 through 16 show a steady decline in modeled lake levels during a relatively dry period to about 1.5 feet City Datum. Between years 16 and 36, modeled lake levels fluctuate in response to relatively normal climatic conditions and show an increasing trend through the period, rising again to about 11 feet City Datum. Years 36 to 44 simulate a "design drought" period[24] more severe than any observed historical drought, and modeled lake levels decline over this eight-year period to a low of -0.8 feet City Datum. In the three years following the drought, modeled lake levels recover to about 5 feet City Datum.

Predicted Lake Levels under the Proposed Project Relative to Modeled Existing Conditions

For the purposes of this EIR, changes in water surface elevation modeled for the GSR Project are compared to changes predicted under the modeled existing conditions scenario to determine whether water surface elevation changes resulting from the proposed Project would be *significant*

[24] The SFPUC measures water supply reliability using an 8.5-year "design drought." A design drought is a planning and operations tool used by water agencies to define a reasonable worst-case drought scenario in order to establish design and operating parameters for the water system. The WSIP uses a design drought based on the hydrology of the six years of the worst historical drought (1987-1992) on record, plus the 2.5 years of the 1976-1977 drought, for a combined total of an 8.5-year design drought sequence.

when compared to the modeled existing conditions in the context of the effects of varying lake levels on biological resources.

Similar to the modeled existing conditions model, under the proposed Project water levels would also respond to modeled climatic variations in the same hydrologic sequence pumping (see Figures 5.16-11 [Simulated Lake Merced Level Changes] and 5.16-12 [Simulated Lake Merced Levels Relative to Modeled Existing Conditions]). Maximum lake levels over the model period are predicted at 13 feet City Datum, or 0.6 feet above the modeled existing conditions maximum. Minimum lake levels could reach as low as -2.5 feet City Datum, or 1.7 feet below the modeled existing conditions minimum water surface elevation (Kennedy/Jenks 2012).

Compared to the modeled existing conditions, the modeled water levels for the GSR Project (see Figures 5.16-11 and 5.16-12) show a similar initial sharp increase in lake levels from 5.7 feet City Datum to over 12 feet City Datum. Lake levels predicted to result from operation of the Project increase by about 5 feet as compared to modeled existing conditions in Years 1 through 10. This relative difference is maintained by the simulation over climatic variations until the start of the design drought in Year 36. During the design drought, lake levels drop to the predicted minimum of -2.5 feet City Datum and then slowly begin to rise again to reach about 2 feet City Datum at the end of the model period, where water levels are predicted to be about 4 feet lower than predicted under the modeled existing conditions.

Impact BR-6: Operation of the Project would not adversely affect species identified as candidate, sensitive, or special-status wildlife species in local or regional plans, policies, or regulations, or by the CDFW or USFWS. (Less than Significant)

For special-status nesting birds, Project-related water surface elevation decreases of 0.5 feet or more over a 2.5-week period in any single nesting season (conservatively March 1 through August 15) would be considered to result in a *significant* impact on reproductive success. If water level decreases were to occur rapidly, nests could be stranded, resulting in the loss of nests and eggs and thus adversely affecting productivity. It is presently unknown whether western pond turtle are reproducing at Lake Merced. If they are, a water level rise of greater than 3 feet in any given year (measured from March 1st to March 1st) could potentially inundate western pond turtle nests, causing reproductive failure and/or hatchling mortality and would be considered *significant* if the increase were caused by the Project.

A summary of estimates generated by the Lake Merced Lake-Level Model for the modeled existing conditions, as well as the proposed Project, shows that the Project is predicted to result in a maximum modeled monthly lake level decrease of 0.04 feet (Kennedy/Jenks 2012). Therefore, relative to the significance threshold of 0.5 feet over a 2.5-week period, the Project would have a *less-than-significant* impact on the reproductive success of special-status birds nesting at or near the water line and no mitigation is required.

The summary of estimates presented in Attachment 10.2-A of Technical Memorandum 10.2 also include a summary of the predicted annual range between maximum and minimum lake levels possible under the various scenarios (Kennedy/Jenks 2012). As summarized therein and below in Table 5.14-11 (Summary of Predicted Annual Range in Lake Levels), the predicted mean modeled annual lake level elevation range is 1.6. This means that most of the time, modeled lake levels are expected to increase or decrease from the average annual water surface elevation by 0.8 foot. Under the most extreme conditions, such as during a series of above-normal precipitation years, the modeled existing conditions for lake levels are predicted to fluctuate as much as 2.25 feet above or below the predicted average annual water surface elevation in a single year. With implementation of the GSR Project, maximum lake level rise in one year is predicted to be only slightly greater at 2.35 feet; i.e., an increase of only 0.10 foot. Therefore, relative to the significance threshold and modeled existing conditions, the Project would have a *less-than-significant* impact on nesting western pond turtles, and no mitigation is required.

TABLE 5.14-11
Summary of Predicted Annual Range in Lake Levels

Predicted Lake Level Change	Modeled Existing Conditions (feet)	Project (feet)	Difference in Change Between Modeled Existing Conditions and the Project (feet)
Maximum annual range	5.5	5.6	+0.10
95th percentile	3.2	2.8	-0.4
90th percentile	2.7	2.7	0.0
Mean lake level range	1.6	1.5	-0.10

Source: Kennedy/Jenks 2012

Impact Conclusion: Less than Significant

Impact BR-7: Operation of the Project could adversely affect sensitive habitat types associated with Lake Merced. (Less than Significant with Mitigation)

The following have been identified as sensitive vegetation and habitat types at Lake Merced: dune scrub, thimbleberry, wax myrtle, and canyon live oak scrubs, Vancouver rye grassland (perennial grassland), fish-related habitat, wetlands (including arroyo willow riparian scrub), and blue gum eucalyptus forest. Impacts on wetlands are discussed below in Impact BR-8 and impacts on eucalyptus forest are discussed in Impact BR-9. Potential Project-related impacts on the remaining sensitive habitat types are discussed here.

Dune, Thimbleberry, Wax Myrtle, and Canyon Live Oak Scrubs, and Vancouver Rye Grassland Habitat

As discussed in the Section 5.14.3.2 (Approach to Analysis) under Significance Thresholds, reductions of the dune scrub, thimbleberry, wax myrtle, and canyon live oak scrubs, or Vancouver rye grassland (perennial grassland) habitats at Lake Merced would be considered *significant* if losses were to exceed 10 percent, when compared to the modeled existing conditions, for any of these single habitat types. Based on the vegetation analysis and additional GIS-based analysis comparing elevation contours with locations of sensitive biological resources, Table 5.14-12 (Predicted Loss of Sensitive Communities with Rising Water Levels) shows how sensitive plant communities are predicted to decrease with rising water surface elevations and shows the predicted water surface elevation at or near which effects are predicted to begin for each sensitive plant community. The presence of these species is not specifically dependent on water levels and it is expected that, due to their rarity and small patch size around the lake, they would not likely reestablish if they were inundated and then water levels recede. Therefore, unlike changes for wetlands, discussed below in Impact BR-8, predicted vegetation losses for these vegetation types, once they are inundated, are considered permanent and the elevations at which they are affected are considered absolute.

TABLE 5.14-12
Predicted Loss of Sensitive Communities with Rising Water Levels[(a)]

	Acres at Mean Annual Water Surface Elevations of 6 to 13 feet and Percent Change (City Datum)							
Sensitive Community	**6 feet**	**7 feet**	**8 feet**	**9 feet**	**10 feet**	**11 feet**	**12 feet**	**13 feet**
Dune scrub	3.30	3.30	3.29	3.29	3.28	3.24	3.19	3.13
Percent change	--	-0.06%	-0.15%	-0.36%	-0.73%	-1.73%	-3.19%	-5.02%
Canyon live oak scrub	--	--	0.13	0.13	0.13	0.13	0.12	0.12
Percent change	--	--	--	-0.08%	-1.31%	-2.62%	-7.00%	**-10.31%**
Wax myrtle scrub	--	--	0.08	0.08	0.07	0.05	0.03	0.01
Percent change	--	--	--	-2.00%	**-11.25%**	**-36.50%**	**-65.50%**	**-87.00%**
Vancouver rye grassland	--	--	0.013	0.012	0.007	0.005	0.002	0.001
Percent change	--	--	--	-8.59%	**-40.17%**	**-57.81%**	**-82.81%**	**-93.75%**

Note:

(a) Values in **bold** indicate the water surface elevation where a habitat loss of 10 percent or greater is predicted to occur. All acreage calculations were performed in GIS and therefore have a high degree of precision. However, this GIS analysis may not precisely predict actual changes in habitat on the ground, especially at very small scales.

As shown on Table 5.14-12 (Predicted Loss of Sensitive Communities with Rising Water Levels), it is estimated that water surface elevations between 12 and 13 feet City Datum would result in loss of 5 percent of dune scrub habitat at Lake Merced. The losses would be expected to occur primarily at Impound Lake in areas where several special-status plant species have been mapped recently (May & Associates 2009; Nomad Ecology 2011), although most special-status plant populations at Lake Merced are located above 13 feet City Datum. A water level rise to 13 feet City Datum at Impound Lake could also inundate and kill small populations of coastal black gooseberry, although that species is not precisely mapped (SFRPD 2006), and Wight's paintbrush, which occur in coastal scrub on the southeastern shore. It is estimated that thimbleberry scrub would not be inundated by rising water surface elevations under any scenario, as it occurs entirely above the elevation of the spillway at 13 feet City Datum. However, a 10 percent loss of canyon live oak scrub is predicted to occur between water surface elevations 12 and 13 and a 9 percent loss of wax myrtle scrub is predicted to occur at 10 feet City Datum. These vegetation types are not expected to regenerate naturally since the spread of canyon live oak is constrained by other upland vegetation types and the wax myrtle scrub was planted and is also constrained by other upland vegetation types. So the losses would be assumed permanent. Finally, it is estimated that water surface elevations exceeding 9 feet City Datum would result in loss of more than 10 percent of Vancouver rye grassland at Lake Merced.

Should Project operations result in water level increases above the water surface elevations described above, and the change in habitat attributed to the Project were greater than 10 percent, a *significant* impact would occur. In order to determine the Project's contribution to habitat loss potential, the GIS-based analysis was used to predict habitat acreages for the model period where the predicted Lake Merced water surface elevation resulting from the Project, compared to the predicted water surface elevation for the modeled existing condition, is greatest. This represents the potential 'worst case' acreage loss for each habitat type and is represented in model year 22 where modeled existing conditions reflect a normal climactic water year and the GSR Put Period is near completion.

The predicted water surface elevation for modeled existing conditions in model year 22 is 7 feet City Datum, while the predicted water surface elevation for the Project is approximately 12.8 feet City Datum, which is also the predicted maximum lake level under the Project over all model years. Therefore, water levels resulting from implementation of the Project are predicted to exceed the water surface elevations where substantial loss of canyon live oak scrub, wax myrtle scrub, and Vancouver rye grassland could occur, and, as a result, the acreage loss as a result of the Project is predicted to be greater than 10 percent. Table 5.14-13 (Comparison of Predicted Sensitive Community Acreages under Modeled Existing Conditions and the Project) compares the predicted modeled existing conditions acreages for sensitive habitats with the acreages predicted under the Project, and the percentage of acreage lost, for model year 22.

TABLE 5.14-13
Comparison of Predicted Sensitive Community Acreages under Modeled Existing Conditions and the Project[(a)]

Vegetation Community	Acreages Resulting from Modeled Existing Conditions (Model Year 22)	Acreages Resulting from Implementation of the Proposed Project (Model Year 22)	Difference in Acreages Resulting from Implementation of the Proposed Project as Compared to Modeled Existing Conditions	Percent Change Resulting from Implementation of the Proposed Project as Compared to Modeled Existing Conditions
Central dune scrub	3.30	3.13	-0.17	-5%
Canyon live oak scrub	0.13	0.12	-0.01	-10%
Wax myrtle scrub	0.08	0.01	-0.07	-87%
Perennial grassland (Vancouver rye grassland)	0.013	0.001	-0.012	-92%

Note:

(a) Based on modeled water surface elevations of 7 feet City Datum for modeled existing conditions and 12.8 feet City Datum for the proposed Project. Since the vegetation change analysis is based on whole number increments of change, acreages at 13 feet City Datum are given.

As shown on Table 5.14-13 (Comparison of Predicted Sensitive Community Acreages under Modeled Existing Conditions and the Project), the maximum loss of central dune scrub is predicted to be less than 10 percent as a result of the Project. Thus, impacts on this habitat type would be *less than significant*. However, relative to modeled existing conditions, canyon live oak scrub losses may slightly exceed 10 percent and losses of wax myrtle scrub and perennial grassland are predicted to substantially exceed 10 percent; thus, the impacts on these habitats would be *significant*. However, implementation of Mitigation Measure M-BR-7 (Lake Level Management for Water Levels Increases for Lake Merced) would serve to reduce potential impacts on canyon live oak scrub, wax myrtle scrub, and Vancouver rye grassland resulting from Project implementation to *less-than-significant* levels through management of water levels to avoid Project-related losses of sensitive communities. Mitigation Measure M-BR-7 (Lake Level Management for Water Levels Increases for Lake Merced) includes a requirement that Lake Merced water levels be maintained at no more than 9 feet City Datum, or the level that would occur without the Project based on lake-level modeling, whichever is higher. As shown on Table 5.14-13, a water surface elevation of 9 feet City Datum is predicted to result in a less than 10 percent loss of canyon live oak scrub and wax myrtle scrub and therefore, with implementation of Mitigation Measure M-BR-7 (Lake Level Management for Water Levels Increases for Lake Merced), loss of Vancouver rye grassland resulting from Project operation are predicted to be less than 10 percent. Should water levels without the Project be expected to exceed 9 feet City Datum, maintenance of Project-related water surface elevations at the same level as expected without the Project would ensure that loss of habitat is limited to that which would be expected to occur naturally.

Fisheries and Fish Habitat

Rising water levels associated with modeled existing conditions are not expected to have a *significant* impact on Lake Merced fisheries, given that rising water levels would increase the volume of fish habitat overall and would not substantially degrade the quality of fish habitat for warmwater or cold water fish species, because water clarity would not be degraded by rising water levels and temperature decreases would be small and within the normal range of fish species that inhabit an inland coastal lake (EDAW 2004). However, decreasing water levels could substantially reduce aquatic habitat and degrade water quality, thereby negatively affecting fish populations through impacts on fish habitat-related beneficial uses, which would be considered *significant* by this analysis. While no significant impacts on beneficial uses are expected due to a rise in water surface elevations, as noted in Section 5.16, Hydrology and Water Quality, water level decreases below 0 feet City Datum, which are predicted to occur under modeled existing conditions, could result in decreases in water quality with resulting adverse effects on fish-related beneficial uses

Under the modeled existing conditions, lake levels are predicted to drop as low as -0.8 feet City Datum. At about 4 feet City Datum, all of the individual lakes are hydraulically connected and below this water level, reduced hydraulic connection would eliminate water exchanges between these water bodies. Lake volume would decrease and thus lake temperatures and eutrophication would be expected to increase, as would periods of low dissolved oxygen. These factors could combine to lower water quality, resulting in adverse effects on beneficial uses related to fish habitat, as described above in the discussion on significance thresholds for fisheries and fish habitat in Section 5.14.3.2 (Approach to Analysis).

Relative to modeled existing conditions, the proposed Project is predicted to result in water levels approximately 5 feet higher for most of the modeled time period and, during that time, would have *less-than-significant* impacts on fisheries or fish habitat similar to conditions that are predicted to occur under modeled existing conditions when lake levels rise. However, during drought periods, water levels could reach as low as -2.5 feet City Datum, or nearly 2 feet lower than the predicted minimum for modeled existing conditions. This could mean a further significant decrease in water quality from modeled existing conditions, which would be attributable to the Project. However, Mitigation Measure M-HY-9a (Lake Level Monitoring and Modeling for Lake Merced) (see Section 5.16, Hydrology and Water Quality) and Mitigation Measure M-BR-7 (Lake Level Management for Water Levels Increases for Lake Merced), require the SFPUC to implement lake level management procedures to maintain Lake Merced at water levels due to the Project at or below 9 feet City Datum and Mitigation Measure M-HY-9b requires the SFPUC to maintain water levels due to the Project at or above 0 feet City Datum. Implementation of this mitigation measure would therefore also serve to mitigate potential *significant* impacts on the fish habitat-related beneficial uses of Lake Merced through management of water levels to avoid a significant Project-related degradation of water quality (SFPUC 2013).

Mitigation Measure M-HY-9a: Lake Level Monitoring and Modeling for Lake Merced
(see Impact HY-9 in Section 5.16, Hydrology and Water Quality for a description)

Mitigation Measure M-HY-9b: Lake Level Management for Lake Merced
(see Impact HY-9 in Section 5.16, Hydrology and Water Quality for a description)

Mitigation Measure M-BR-7: Lake Level Management for Water Level Increases for Lake Merced
In addition to ongoing monitoring and evaluation of lake levels, as well as maintenance of the Lake-level Model so as to be able to evaluate what lake levels may have been without implementation of the Project based on the actual hydrology that occurs during Project implementation, as described in Mitigation Measure M-HY-9a (Lake Level Monitoring and Modeling for Lake Merced), the SFPUC shall implement corrective action if lake levels increase to 9 feet City Datum as an annual average due to the Project. Corrective action shall be taken to reduce the lake levels to 9 feet City Datum or less. These actions may include one of more of the following, which would result in lowering groundwater levels and thereby indirectly lowering lake levels:

- Temporarily suspend in-lieu delivery of surface water supplies to Daly City so that Daly City would increase pumping from Daly City wells.
- Increase pumping from GSR wells at Sites 1 through 4, which are within 1.5 miles of Lake Merced.

Impact Conclusion: Less than Significant with Mitigation

Impact BR-8: Operation of the Project could adversely affect wetland habitats and other waters of the United States associated with Lake Merced. (Less than Significant with Mitigation)

In order to determine the proposed Project's effect on wetlands, the thresholds of no-net-loss of wetlands were compared with the simulated Lake Merced lake levels (Kennedy/Jenks 2012) to assess whether wetland impacts would be expected occur under the Project and cumulative scenarios, relative to the modeled existing conditions scenario.

Wetland extent at Lake Merced is determined primarily by water levels and topography, and has moved up slope with the water levels over time (Stillwater 2009; Nomad Ecology 2011). As seen in Table 5.14-13 (Comparison of Predicted Sensitive Community Acreages under Modeled Existing Conditions and the Project), there are five distinct freshwater marsh and seasonal wetland types at Lake Merced and the wetlands vegetation type is one of the most widespread around the lake, although overall wetland acreage has decreased since 2002 as mean annual lake levels have risen. As noted above, willow riparian scrub has also decreased in acreage since 2002. As lake levels rise and fall, emergent wetlands are expected to follow closely, as willow riparian scrub would, although relative proportions of the various wetland types are expected to change as they move upslope and downslope, depending on topography and adjacent plant communities. Since this basic pattern has been observed and is borne out in the predictions of the GIS-based vegetation change analysis, it is predicted to continue to occur over the time period modeled for the various scenarios under consideration in this EIR.

The predicted vegetation response to rising or declining water levels would differ depending on the baseline water level for a given period, which changes annually due to natural hydrological variation independent of Project operation. Additionally, the amount of shoreline available for wetland establishment at a given water surface elevation differs according to the topography of the lakeshore, which generally is steeper at higher elevations and flatter at lower elevations. The GIS-based analysis predicted vegetation changes for increasing and decreasing water levels compared to each potential water level change, as shown in Appendix J (Lake Merced Vegetation Change Analysis Methodology). As an example of the predicted vegetation changes for increasing and decreasing water levels compared to a baseline value, Table 5.14-14 (Predicted Change in Vegetation Acreages and Percent Change Relative to a 6-foot Water Surface Elevation: Rising Water Levels) presents a summary of the predicted vegetation changes for increasing water levels, compared to a water surface elevation of approximately 6 feet City Datum, while Table 5.14-15 (Predicted Change in Vegetation Acreages and Percent Change Relative to a 6-foot Water Surface Elevation: Receding Water Levels) summarizes predicted vegetation changes for decreasing water levels compared to the same baseline water surface elevation.

Notes:

(a) Acreages in the table are for vegetation at and below 13 feet City Datum

(b) Vegetation change is measured against a baseline of 6-foot (City Datum) mean annual water surface elevation.

(c) Percent change is relative to vegetation acreage at 6 feet City Datum.

All upland vegetation types were combined for the analysis of receding lake levels.

Values in **bold** indicate an increase in cover type.

Values in *italic* indicate a decrease in cover type.

Under the example where the water surface elevation is approximately 6 feet City Datum, the vegetation change analysis predicts incremental increases in wetlands at average annual water surface elevations between 7 and 11 feet City Datum (Table 5.14-14 [Predicted Change in Vegetation Acreages and Percent Change Relative to a 6-foot Water Surface Elevation: Rising Water Levels]), with a net loss occurring between 6 and 7 feet City Datum and between 11 and 13 feet City Datum. This is due primarily to the fact that between 6 and 12 feet City Datum, water level increases would inundate several large areas of low gradient topography at depths conducive to emergent wetland establishment (between -5 and 2 feet above the water surface elevation). Above 11 feet City Datum, topography begins to steepen, which reduces the area available for wetland colonization because lake depths increase more rapidly and there is less area for wetland species to grow. The analysis also predicts loss of wetlands at water surface elevations lower than 6 feet City Datum, and continuing down to -6 feet City Datum. Again, this is due primarily to topography, as areas of low gradient topography allow for areas of greater wetland establishment and when topography steepens, wetland establishment is restricted by more rapidly increasing water depths. Then wetland acreage begins to increase again to above the estimated baseline acreage between -5 and -10 feet City Datum. Above 6 feet City Datum, bulrush wetlands are predicted to increase in extent at each incremental rise up to 12 feet City Datum and then decrease between 12 and 13 feet City Datum but still remain above the acreage mapped in 2012. Bulrush wetlands are predicted to replace willow scrub, as this vegetation type would die with prolonged inundation, as well as knotweed wetlands, due primarily to changes in topography and water depth. Below 6 feet City Datum, the extent of the various emergent wetland types would vary with elevation and topography relative to water surface elevations, with initial losses primarily of bulrush wetland and increases in the other emergent types, as well as willow scrub. Losses would occur in non-bulrush wetlands generally between 2 and -8 feet City Datum and then increases in all wetland types would occur at the low end of the water surface elevation range.

In general, the predicted vegetation areas compare relatively well with those documented in previous studies at lower water surface elevations (see Table 5.14-15 [Predicted Change in Vegetation Acreages and Percent Change Relative to a 6-foot Water Surface Elevation: Receding Water Levels]). However, for bulrush, there are considerable differences between the current analysis and observations at lower water levels. In part, this may be explained by the uncertainty inherent in predicting patterns of establishment on newly exposed terrain, as described above. In addition, this analysis recognizes that earlier accounts of the extent of bulrush were effectively under rising water surface elevation conditions. For example, bulrush that established when the water surface elevation was at 0 feet City Datum would likely persist when the water rises to 5 feet City Datum. In contrast, bulrush would not establish as readily in deeper water as the water surface drops, so the amount of area available to colonize, in the near term, would be more limited.

As described above, for each water surface elevation that could occur due to hydrologic conditions alone, the GIS-based vegetation change analysis conducted for this EIR predicts that there is an elevation range within which there would be no net loss as a result of the Project, as shown in Appendix J (Lake Merced Vegetation Change Analysis Methodology), and summarized in Table 5.14-16 (Lake Merced Water Surface Elevation Range that Results in a Predicted No-Net-Loss of Wetlands). If Project operations were to exceed the identified ranges, then a net wetlands loss is predicted to occur and, therefore, a *significant* impact on wetlands would result. For example, if the water surface elevation without the Project was projected to be 8 feet City Datum, there would be no project-related effect on wetlands if the water surface elevation was between 7 feet and 11 feet City Datum.

TABLE 5.14-16
Lake Merced Water Surface Elevation Ranges that Result in a Predicted No-Net-Loss of Wetlands[(a)(b)]

Modeled Water Surface Elevation without the Project (City Datum)	Corresponding Project-Related Water Surface Elevation Resulting in a Predicted No-Net-Loss of Wetlands (City Datum)
13 feet	No restriction needed
12 feet	4 to 12 feet
11 feet	9 to 11 feet
10 feet	9 to 11 feet
9 feet	8 to 11 feet
8 feet	7 to 11 feet
7 feet	4 to 11 feet
6 feet	5 to 11 feet
5 feet	4 to 11 feet; -6 to -10 feet
4 feet	3 to 12 feet; -5 to -10 feet
3 feet	2 to 12 feet; -5 to -10 feet
2 feet	1 to 12 feet; -4 to -10 feet
1 feet	0 to 12 feet; -3 to -10 feet
0 feet	-10 to 12 feet
-1 feet	-10 to 12 feet
-2 feet	0 to 12 feet; -2 to -10 feet
-3 feet	1 to 12 feet; -3 to -10 feet
-4 feet	1 to 12 feet; -4 to -10 feet
-5 feet	3 to 12 feet; -5 to -10 feet
-6 feet	8 to 11 feet; -6 to -10 feet
-7 feet	-7 to -10 feet
-8 feet	-8 to -10 feet
-9 feet	-9 to -10 feet
-10 feet	-10

Note:

(a) The water surface elevation values used represent the predicted annual average water surface elevations. Lake Merced water levels vary seasonally due to hydrologic and climatic conditions; therefore, an annual average range in water surface elevation from about 1 foot above and below the mean is assumed. For example, an elevation of 6 feet City Datum, as seen in Table 5.14-16 (Lake Merced Water Surface Elevation Range that Results in a Predicted No-Net-Loss of Wetlands), actually represents a range in water surface elevation between 5 feet and 7 feet City Datum.

(b) According to Mitigation Measure M-BR-7 (Lake Level Management for Water Level Increases for Lake Merced), Lake Merced lake levels would be prohibited from exceeding 9 feet City Datum, so some of the lake levels that would be acceptable relative to wetlands impacts would not be acceptable relative to sensitive habitats.

In order to distinguish the Project's predicted contribution to effects on wetland habitats from the predicted effects of the modeled existing conditions (i.e., to calculate the Project's incremental effect), the threshold for a net loss of wetlands was compared with the simulated Lake Merced water levels (Kennedy/Jenks 2012) to assess whether impacts would occur. During some of the modeled years, no net loss, or even wetlands gains, are expected to occur, while in other years, wetlands losses are expected. For instance, as shown on Figures 5.16-11 (Simulated Lake Merced Level Changes) and 5.16-12 (Simulated Lake Merced Levels Relative to Modeled Existing Conditions), the lake level predicted under modeled existing conditions for model year 16 is approximately 6 feet City Datum and lake level predicted under Project conditions is approximately 7 feet City Datum. As shown on Table 5.14-16 (Lake Merced Water Surface Elevation Range that Results in a Predicted No-Net-Loss of Wetlands), when the water surface elevation without the Project is predicted to be 6 feet (see the row with "6 feet" in the column labeled "Water Surface Elevation without the Project [City Datum]"), an increase of up to 5 feet resulting from Project operations could occur without resulting in loss of wetlands (i.e. the acceptable water surface elevation would be 5 to 11 feet). Therefore, the increase of 1 foot over conditions without the Project that is predicted in model year 16 would not result in a net loss of wetlands. However, the lake level predicted under modeled existing conditions for model year 22 is approximately 7 feet City Datum, whereas the lake level predicted under Project conditions for that same year is approximately 12 feet City Datum. Model year 22 represents modeled existing conditions under a normal climatic water year during a Put Period, and is the year when the difference between the two lake levels is predicted to be the greatest. As shown on Table 5.14-16, when the water surface elevation without the Project is predicted to be 7 feet City Datum, an increase of up to 4 feet resulting from Project operations (which would be up to 11 feet City Datum) could occur without resulting in a net loss of wetlands. Therefore, the increase of 5 feet over conditions without the Project (which would be 12 feet City Datum) that is predicted in model year 22 would result in loss of wetlands, which would be a *significant* impact. The lake levels following the design drought (model year 44) are predicted to be approximately 1 foot City Datum for modeled existing conditions and approximately -2 feet City Datum for the Project, which would also result in a net loss of wetlands, because the decline from a 1 foot City Datum elevation without the Project would need to be greater than 4 feet City Datum to avoid wetland loss (per Table 5.14-16). However, implementation of Mitigation Measures M-BR-8 (Lake Level Management for No-Net-Loss of Wetlands for Lake Merced), M-HY-9a (Lake Level Monitoring and Modeling for Lake Merced), and M-HY-9b (Lake Level Management for Lake Merced) would maintain water levels in a way that would mitigate wetlands impacts to *less-than-significant* levels. Under Mitigation Measures M-BR-8 (Lake Level Management for No-Net-Loss of Wetlands for Lake Merced) and M-HY-9b (Lake Level Management for Lake Merced), for each water surface elevation that could occur due to hydrologic conditions alone (i.e., first column of Table 5.14-16), the GIS-based vegetation change analysis conducted for this EIR indicates the elevation range within which no net loss of wetlands would occur as a result of the Project (i.e., last column of Table 5.14-16). Mitigation Measure M-BR-8 (Lake Level Management for No-Net-Loss of Wetlands for Lake Merced) and M-HY-9b (Lake Level Management for Lake Merced) require that lake levels be maintained within these ranges (i.e., right-hand column of Table 5.14-16), thereby reducing potential impacts on wetlands resulting from Project implementation to *less-than-significant* levels.

Mitigation Measure M-HY-9a: Lake Level Monitoring and Modeling for Lake Merced
(See Impact HY-9 in Section 5.16, Hydrology and Water Quality for a description)

Mitigation Measure M-HY-9b: Lake Level Management for Lake Merced
(See Impact HY-9 in Section 5.16, Hydrology and Water Quality for a description)

Mitigation Measure M-BR-8: Lake Level Management for No-Net-Loss of Wetlands for Lake Merced
In addition to ongoing monitoring, evaluation of lake levels, and maintenance of the Lake-level Model so as to be able to evaluate what lake levels may have been without implementation of the Project based on the actual hydrology that occurs during Project implementation, as described in Mitigation Measure M-HY-9a (Lake Level Monitoring and Modeling for Lake Merced), the SFPUC shall implement corrective action if lake levels exceed the range of lake level changes shown in Table 5.14-16 (Lake Merced Water Surface Elevation Range that Results in a Predicted No-Net-Loss of Wetlands), due to the Project (i.e., the right-hand column). Note that according to Mitigation Measure M-BR-7 (Lake Level Management for Water Level Increases for Lake Merced), Lake Merced lake levels due to the project would be prohibited from exceeding 9 feet City Datum, so some of the higher lake levels that would be acceptable relative to wetlands impacts as identified in Table 5.14-16 would not be acceptable relative to sensitive habitats. In addition, according to Mitigation Measure M-BR-9b (Lake level Management for Lake Merced), Lake Merced lake levels due to the Project would be prohibited from decreasing below 0 feet City Datum, so some of the lower lake levels that would be acceptable relative to wetlands impacts identified in Table 5.14-16 would not be acceptable relative to water quality and associated beneficial uses.

Corrective actions may include one or more of the following, which would result in the lowering of groundwater levels and thereby indirectly lowering lake levels:

- Suspend in-lieu delivery of surface water supplies to Daly City. Daly City would thus increase pumping from Daly City wells, which would lower groundwater levels in the vicinity of Lake Merced.
- Increase pumping from GSR wells at Sites 1 through 4, which are within 1.5 miles of Lake Merced.

Impact Conclusion: Less than Significant with Mitigation

Impact BR-9: Operation of the Project could adversely affect native wildlife nursery sites associated with Lake Merced. (Less than Significant with Mitigation)

As discussed in Section 5.14.3.2 (Approach to Analysis), large eucalyptus along the shores of North and South Lakes support several double crested cormorant and great blue heron rookeries. A loss of 10 percent or more of the eucalyptus forest around Lake Merced, particularly the more isolated stands, as a result of the proposed Project would be considered significant for the purposes of this EIR. Table 5.14-17 (Predicted Loss of Eucalyptus Forest with Rising Water Levels) shows how eucalyptus forest is predicted to decrease with rising water surface elevations and shows the predicted average annual water surface elevation at or near which effects are predicted to begin. As shown, the results of the vegetation modeling prepared for this EIR indicate that a 10 percent loss of eucalyptus forest would begin to occur at a water surface elevation of 8 feet City Datum. However, since the vegetation mapping relies on aerial photograph interpretation of the canopy and individual eucalyptus stems were not mapped, the potential losses at this elevation are likely overestimated. Currently, there are healthy eucalyptus trees at the high water line. Most trees are located at higher elevations than that, and on steeper slopes the trunks may be located well above the 8 foot contour. Therefore, it is conservatively assumed by this EIR analysis that a substantial loss of eucalyptus forest would occur if a water surface elevation of 9 feet City Datum were to be exceeded and persist for more than one month. Similar to impacts on scrub and grassland habitat (see Impact BR-7), the presence of eucalyptus is not specifically dependent on water levels and it is expected that, while they could reestablish if they were inundated and then water levels were to recede, it would be decades before new trees could grow to a size sufficient to support a rookery. Predicted eucalyptus loss following inundation is considered by this analysis to be permanent, and the elevation at which this habitat is affected is considered absolute.

TABLE 5.14-17
Predicted Loss of Eucalyptus Forest with Rising Water Levels[(a)]

Sensitive Community	Acres of Eucalyptus Forest at Mean Annual Water Surface Elevation (City Datum)							
	6 feet	**7 feet**	**8 feet**	**9 feet**	**10 feet**	**11 feet**	**12 feet**	**13 feet**
Blue gum eucalyptus forest	17.63	17.24	15.79	14.93	14.39	13.96	13.58	13.22
Percent change[(b)]	--	-2.24%	**10.42%**	**-15.30%**	**-18.37%**	**-20.83%**	**-22.98%**	**-25.04%**

Notes:

(a) Values in **bold** indicate an increase in cover type.

(b) Due to canopy cover over the lake shoreline, the predicted change for blue gum eucalyptus is likely overestimated.

Should Project operations result in water level increases above 9 feet City Datum that persist for more than one month, and the change in habitat attributed to the Project were 10 percent or greater, a *significant* impact on this wildlife nursery site would occur. In order to determine the Project's contribution to this potential habitat loss, the GIS-based analysis was used to predict habitat acreages for the model period where the predicted Lake Merced water surface elevation resulting from the Project, compared to the water surface elevation for the modeled existing condition is greatest, similar to the analysis described in Impact BR-7. This would represent the potential 'worst case' acreage loss for each habitat type, and is represented in model year 22 where modeled existing conditions reflect a normal climatic water year and the GSR Put Period is near completion. The predicted water surface elevation for modeled existing conditions in model year 22 is 7 feet City Datum, while the predicted water surface elevation for the Project is approximately 12 feet City Datum. Therefore, water levels resulting from implementation of the Project are predicted to exceed the water surface elevations of 9 feet City Datum, the elevation at which the Project could result in a loss of blue gum eucalyptus forest of 10 percent or more. Table 5.14-18 (Comparison of Eucalyptus Forest Acreages with Predicted Acreages under Modeled Existing Conditions and the Project) compares the modeled existing conditions acreages for eucalyptus with the acreages predicted under the Project, and the percentage of acreage lost, for model year 22.

TABLE 5.14-18
Comparison of Eucalyptus Forest Acreages with Predicted Acreages under Modeled Existing Conditions and the Project[(a)]

Vegetation Community	Predicted Acreages Resulting from Modeled Existing Conditions (Model Year 22)	Predicted Acreages Resulting from Implementation of the Proposed Project (Model Year 22)	Difference in Predicted Acreages Resulting from Implementation of the Proposed Project as Compared to Modeled Existing Conditions	Predicted Percent Change Resulting from Implementation of the Proposed Project as Compared to Modeled Existing Conditions
Blue gum eucalyptus forest	17.24	13.58	-3.66	-21%

Note:

Based on modeled water surface elevation of 7 feet City Datum for modeled existing conditions and 12 feet City Datum for the proposed Project.

As shown on Table 5.14-18 (Comparison of Eucalyptus Forest Acreages with Predicted Acreages under Modeled Existing Conditions and the Project), the predicted loss of eucalyptus forest would exceed 10 percent; thus, the impact on native wildlife nursery sites would be *significant*. However, implementation of M-HY-9a (Lake Level Monitoring and Modeling for Lake Merced) and Mitigation Measure M-BR-7 (Lake Level Management for Water Level Increases for Lake Merced) would serve to reduce potential impacts on eucalyptus forest resulting from Project implementation to *less-than-significant* levels through management of water levels to avoid Project-related losses of this habitat, along with other sensitive communities (see Impact BR-7). Mitigation Measure M-BR-7 (Lake Level Management for Water Level Increases for Lake Merced) includes a requirement that Lake Merced water levels be maintained at no more than 9 feet City Datum, or the level projected to occur without the Project based on lake level modeling, whichever is higher. Should water levels without the Project exceed 9 feet City Datum, maintenance of Project-related water surface elevations at the same level as expected without the Project would ensure that loss of habitat is limited to that which would be expected to occur naturally (SFPUC 2013.

Mitigation Measure M-HY-9a: Lake Level Monitoring and Modeling for Lake Merced.
(See Impact HY-9 in Section 5.16, Hydrology and Water Quality for a description)

Mitigation Measure M-BR-7: Lake Level Management for Water Level Increases for Lake Merced
(See Impact BR-7 for a description)

Impact Conclusion: Less than Significant with Mitigation

5.14.3.7 Cumulative Impacts

The geographic scope for the analysis of potential cumulative impacts on biological resources consists of the overall region in which the facilities are being constructed. Projects throughout the region could have adverse effects on the same sensitive species and habitats that occur within the GSR Project facility sites. Table 5.14-1 (Plant Communities Present within or near Facility Sites and near Lake Merced) identifies the biological resources that are within the geographic scope of analysis for cumulative biological resources impacts relative to the GSR facility sites. Refer to Figure 5.1-3 (Location of Projects Considered in the Cumulative Analysis) in Section 5.1, Overview for the location of the cumulative projects.

Impact C-BR-1: Construction and operation of the proposed Project could result in significant cumulative impacts related to biological resources. (Less than Significant with Mitigation)

Construction

Impacts on Special-status Species

As discussed in Impact BR-1, construction of the GSR Project would result in potentially *significant* impacts associated with the temporary, construction-related impacts to habitat loss and disruption of breeding and foraging habitat for nesting birds, raptors, bats, and overwintering Monarch butterflies. It is assumed that several of the cumulative projects listed in Table 5.1-3 (Projects Considered for Cumulative Impacts), particularly those projects located in the same geographic area, could adversely affect some of the same special-status species through tree removal and potential disturbance during nesting and breeding season. In particular, the Centennial Village Project (cumulative project I) would include demolition and reconstruction of a large shopping center located 400 feet southwest from the well facility and adjacent to the pipeline installation proposed for GSR Site 16. Both projects include construction activities near trees along Huntington Drive that provide nesting habitat for migratory birds. Therefore, cumulative impacts related to the potential for impacts on special-status species would be *significant*, and the GSR Project's contribution to this cumulative impact could be cumulative considerable, given that without mitigation, it could also result in *significant* impacts on special-status species.

However, as discussed in Impact BR-1, the GSR Project's temporary impacts on special-status species would be reduced to *less-than-significant* levels with implementation of Mitigation Measures M-BR-1a (Protection Measures during Construction for Special-status Birds and Migratory Passerines and Raptors), M-BR-1b (Protection Measures for Special-status Bats during Tree Removal or Trimming), M-BR-1c (Protection Measures during Structure Demolition for Special-status Bats), and M-BR-1d (Monarch Butterfly Protection Measures). These measures address temporary impacts on special-status species by specifying that tree removal occur during the non-breeding season for special-status birds, and by requiring preconstruction surveys to determine if nesting birds are in the area before construction, if trees must be removed during the breeding season. The measures also require special protection measures for special-status bats during tree removal and trimming, and during demolition of buildings, as well as protection measures for Monarch butterflies during tree removal or trimming. Therefore, with implementation of these mitigation measures, the GSR Project's contribution to cumulative impacts related to impacts to special-status species would not be cumulatively considerable (*less than significant*).

Impacts on Riparian Habitat and Other Sensitive Natural Communities

Some of the cumulative projects listed in Table 5.1-3 (Projects Considered for Cumulative Impacts) could result in construction-related temporary disturbance to riparian habitat in the area. In particular, the Holy Cross Cemetery Expansion Project (cumulative project E) would expand the cemetery into areas east of Hillside Boulevard that could support riparian habitat or other natural communities.

As described in Impact BR-2, the GSR Project would potentially impact 305 square feet of Central Coast riparian scrub adjacent to Site 1 during construction. Therefore, because other cumulative projects, such as the Holy Cross Expansion Project, could also result in impacts on Central Coast riparian scrub or other sensitive natural communities, cumulative impacts related to impacts to riparian habitat and other sensitive natural communities would be *significant*, and the GSRs Project's contribution to this cumulative impact could be cumulatively considerable, given that, without mitigation, it could also result in *significant* impacts on sensitive natural communities.

However, the GSR Project's impact on these sensitive biological resources would be reduced to a *less-than-significant* level with implementation of Mitigation Measure M-HY-1 (Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan) and Mitigation Measure M-BR-2 (Avoid Disturbance to Riparian Habitat). Implementation of these mitigation measures would ensure the protection of riparian habitat during construction. Therefore, with implementation of these measures, the GSR Project's contribution to cumulative impacts related to the disturbance of riparian habitat and other sensitive natural communities would not be cumulatively considerable (*less than significant*).

Impacts on Jurisdictional Waters

Some of the cumulative projects listed in Table 5.1-3 (Projects Considered for Cumulative Impacts) could result in a temporary impact on, or permanent loss of, jurisdictional waters. The SFPUC's Peninsula Pipeline Seismic Upgrade Project Colma Site (cumulative project D-1) would replace an existing water pipeline that traverses proposed GSR Site 8, with the proposed replacement pipeline to be constructed over an existing culvert that may be part of the headwaters of Colma Creek, and if so, would qualify as jurisdictional waters of the United States.

As described under Impact BR-3, the GSR Project could indirectly degrade waters near Site 9 and Site 11. Therefore, cumulative project impacts on jurisdictional waters could be *significant*, and the GSR Project's contribution to this cumulative impact could be cumulatively considerable, given that without mitigation, it could also result in *significant* impacts on jurisdictional waters.

However, the GSR Project's impact on jurisdictional waters would be reduced to a *less-than-significant* level with implementation of Mitigation Measure M-HY-1 (Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan). The measure requires that an erosion control measures be developed and implemented to control stormwater runoff and reduce the sedimentation of jurisdictional waters. Therefore, with implementation of this measure, the GSR Project's contribution to cumulative impacts related to jurisdictional waters would not be cumulatively considerable (*less than significant*).

Impacts related to Conflicts with Local Policies or Ordinances

Many of the cumulative projects listed in Table 5.1-3 (Projects Considered for Cumulative Impacts) could adversely affect trees that are protected under local tree preservation ordinances and codes, including the San Mateo County Significant and Heritage Tree Ordinances, the City of Daly City Municipal Code, the Town of Colma Municipal Code, the City of South San Francisco Municipal Code, and the City of San Bruno Municipal Code. In particular, the Holy Cross Cemetery Expansion Project (cumulative project E) would expand the cemetery into areas east of Hillside Boulevard that support a variety of trees that would also be regulated under the Town of Colma Municipal Code.

As discussed in Impact BR-4, construction would result in removal or trimming of protected trees both inside and outside the SFPUC right-of-way at well facilities and along pipeline routes. Trees protected by the San Mateo County Tree Ordinance, and the Town of Colma, the City of South San Francisco, and the City of San Bruno Municipal Codes would be affected resulting in potentially *significant* cumulative impacts related to conflicts with local policies or ordinances. Therefore, the GSR Project's contribution to this cumulative impact could be cumulatively considerable, given that without mitigation, it could also result in *significant* impacts on locally protected trees.

However, as discussed in Impact BR-4, the GSR Project's impacts related to conflicts with local tree ordinances would be reduced to *less-than-significant* levels with implementation of Mitigation Measures M-BR-4a (Minimize Impacts on Protected Trees to Avoid Tree Loss), M-AE-1b (Tree Protection Measures), and M-BR-4b (Protected Tree Replacement), which would substantially fulfill the intent of the local tree preservation ordinances and codes by minimizing impacts on protected trees and by requiring replacement trees for any protected trees that are removed. Therefore, with implementation of these measures, the GSR Project's contribution to cumulative impacts related to conflicts with local policies protecting biological resources would not be cumulatively considerable (*less than significant*).

Operations

As discussed under Impact BR-5, only Sites 1, 7 (On-Site Treatment), 12, 18 (Alternate), and the West Lake Pump Station have the potential to produce operational noise and would be located at or near areas that support habitat for special-status birds or migratory passerines or raptors. Of these sites, only Site 12 would be located near a cumulative project, the Peninsula Pipeline Seismic Upgrade Project South San Francisco Site (cumulative project D-2), which would not generate any operational noise. Other than operational noise at these sites, the proposed GSR Project would not have permanent or ongoing impacts on biological resources during operations given that the Project does not include additional habitat disturbance following construction, and operation of the Project would not impact individual species or their habitat. Therefore, no cumulative operational impact on biological resources would occur, and the GSR Project would have no contribution to a *significant* cumulative impact on biological resources during operation (*less than significant*).

Impact C-BR-2: The Project would result in cumulative construction or operational impacts related to special-status species, riparian habitat, sensitive communities, wetlands, or waters of the United States, or compliance with local policies and ordinances protecting biological resources at Lake Merced. (Less than Significant with Mitigation)

Approach to Cumulative Analysis

As noted above, not all projects listed in Table 5.1-3 (Projects Considered for Cumulative Impacts) and shown in Figure 5.1-3 (Location of Projects Considered in the Cumulative Analysis) would affect Lake Merced lake levels and the biological resources supported by the Lake and its surrounding habitats. Specific additional proposed and existing projects that would affect lake levels were considered in this Lake Merced operational cumulative analysis. As noted in greater detail in the cumulative analysis presented in Section 5.16, Hydrology and Water Quality, these include the SFPUC's proposed San Francisco Groundwater Supply (SFGW) Project (cumulative project A-1 through A-6) and Daly City's proposed Vista Grande Drainage Basin Improvement Project (cumulative project B). The former would affect Lake Merced water surface elevations most directly through groundwater pumping and the latter through direct hydrologic input of stormwater to the Lake (Vista Grande), as well as projected pumping by Partner Agencies in the South Westside Groundwater Basin and potentially increased pumping at the Holy Cross cemetery (i.e., other existing projects).

Predicted Lake Merced water levels, under the cumulative scenario conditions, respond to modeled climatic variations in the same hydrologic sequence as was used for the modeled existing conditions (see Figures 5.16-11 [Simulated Lake Merced Level Changes] and 5.16-12 [Simulated Lake Merced Levels Relative to Modeled Existing Conditions]). The mean annual range between the maximum and minimum lake levels under cumulative conditions is predicted to be 1.6 feet City Datum, which is the same as modeled existing conditions, whereas the mean annual range for the GSR Project alone is predicted to be 1.5 feet over the model period. (Kennedy/Jenks 2012)

The maximum lake level (as a monthly average) under cumulative conditions is predicted to be 9.5 feet City Datum, which is 2.9 feet less than the maximum level under modeled existing conditions, and 3.5 feet less than the maximum level for the GSR Project alone. The minimum lake level (as a monthly average) under cumulative conditions is predicted to be -4.9 feet City Datum, which is 4.1 feet lower than the minimum level under modeled existing conditions, and 2.4 lower than the minimum level for the GSR Project alone. Lake Merced water levels under cumulative conditions are predicted to be consistently within 3 feet above or below the level predicted for the modeled existing conditions, except during the modeled design drought, at which time lake levels under cumulative conditions are predicted to be 4 to 5 feet lower than predicted under the modeled existing conditions. (Kennedy/Jenks 2012)

Overall, the cumulative condition is expected to exhibit less dramatic water level fluctuations in most years than those predicted for the GSR Project alone, as the combined cumulative projects would provide hydrologic inputs that would balance the effects of groundwater pumping from the GSR and SFGW projects by themselves. For example, the proposed Vista Grande Drainage Basin Improvement Project is proposed to provide hydrologic inputs to Lake Merced in the form of excess stormwater buffering lake levels losses that would occur due to the GSR Project during dry years. Also, the SFGW Project would increase pumping to the north of the GSR Project, buffering lake level increases that would occur due to the GSR Project during normal and wet years.

Special-status wildlife species

The cumulative scenario model predicts periods of relatively rapid water surface elevation increase and decrease (see Figures 5.16-11 [Simulated Lake Merced Level Changes] and 5.16-12 [Simulated Lake Merced Levels Relative to Modeled Existing Conditions]). However, as the analysis for Impact BR-6 shows, rapid increases and decreases in water levels, if any were to occur, would be associated with natural hydrologic conditions. As indicated, the GSR Project is expected to have an incremental and less-than-cumulatively considerable contribution to any such increases or decreases. Rapid increases could be associated with the proposed Vista Grande Drainage Basin Improvement Project (cumulative project B), depending on the rate of stormwater inputs to the lake, which is not known at this time. However, the SFGW project and other potential increased groundwater pumping would not increase groundwater levels, and lake levels would not increase as a result of the SFGW project. Nevertheless, due to the potential for the Vista Grande project to cause a rapid increase in lake levels, there could be a *significant* cumulative impact on birds nesting at or near the water line, and on nesting pond turtles, if present, at Lake Merced. However, the contribution of the GSR Project to such rapid increases would be at most 0.04 feet (i.e., less than 0.5 inch) per month, which would have negligible effects on bird or pond turtle nesting, and, therefore, the contribution of the GSR Project to such rapid lake level increases would not be cumulatively considerable (*less than significant*)

Sensitive communities

<u>Dune scrub</u>. Under the cumulative scenario, and for the purposes of this analysis, it is assumed that water surface elevations could not rise higher than 9.5 feet City Datum due to relocation of the spillway to that elevation under the Vista Grande Drainage Basin Improvement Project. Not only would the losses predicted under the project-specific analysis be avoided, but there would be no cumulative impact on dune scrub or rare plant populations at Lake Merced, under this assumption (*no impact*).

<u>Locally sensitive coastal scrub types.</u> Thimbleberry scrub would not be inundated by rising water surface elevations under any of the modeled conditions as it occurs entirely above the existing Lake Merced spillway elevation of 13 feet City Datum. For canyon live oak scrub, a significant loss of greater than 10 percent would not occur unless water surface elevations were to rise to between 12 and 13 feet City Datum, as predicted by the GIS-based vegetation change analysis conducted in support of this EIR. Similarly, a significant loss of greater than 10 percent of wax myrtle scrub would not occur unless water surface elevations were to exceed 10 feet City Datum, as also predicted by the vegetation change analysis. Therefore, cumulative impacts on these sensitive communities would be *less than significant*, as water surface elevations are assumed not to exceed 9.5 feet City Datum under the cumulative scenario (*less than significant*).

<u>Vancouver rye grassland.</u> Based on the 2012 vegetation modeling and further GIS analysis prepared for this EIR, a water surface elevation of 9 feet City Datum would result in loss of 8.5 percent of Vancouver rye grassland and a water surface elevation of 10 feet City Datum is predicted to result in a 40 percent loss of Vancouver rye grassland. With implementation of the cumulative projects and an assumed maximum

possible water surface elevation of 9.5 due to the Vista Grande project, it can be assumed that a greater than 10 percent but less than a 40 percent loss would occur. Therefore, the potential cumulative loss of Vancouver rye grassland is considered *significant* by this analysis. However, implementation of Mitigation Measures M-HY-9a (Lake Level Monitoring and Modeling for Lake Merced) and M-BR-7 (Lake Level Management for Water Level Increases for Lake Merced) for the GSR Project would result in water levels being held below 9 feet City Datum, and therefore, with mitigation, the Project's incremental contribution to cumulative impacts on Vancouver rye grassland would not be cumulatively considerable (*less than significant*).

Fisheries and Fish Habitat

As noted in the modeled existing conditions and project-specific impacts analyses, rising water levels are not expected to have a *significant* impact on Lake Merced fisheries or beneficial uses. However, as described in Section 5.16, Hydrology and Water Quality, water levels decreasing below 0 feet City Datum could substantially reduce aquatic habitat and degrade water quality, thereby negatively affecting fish populations and the fish-related beneficial uses of Lake Merced, as well as potentially indirectly impacting special-status birds.

As modeled by Kennedy/Jenks (Kennedy/Jenks 2012), the cumulative scenario operations are predicted to result in water levels above 0 feet City Datum for about 90 percent of the model period and during that time would have no adverse impacts on fisheries or fish habitat. However, during pumping associated with the Take Periods proposed by the Regional Groundwater Storage and Recovery (GSR) Project combined with the proposed SFGW project pumping during the simulated prolonged drought (see Figures 5.16-11 [Simulated Lake Merced Level Changes] and 5.16-12 [Simulated Lake Merced Levels Relative to Modeled Existing Conditions]), water levels are predicted to fall as low as -4.9 City Datum, or 4.1 feet lower than the predicted minimum water surface elevation for modeled existing conditions. Relative to the modeled existing conditions, this would likely result in a further potential for a decrease in water quality from modeled existing conditions. Therefore, a *significant* cumulative impact on water quality could occur. However, for the majority of the approximately 10 percent of the model period where the water surface elevation is predicted to fall below 0 feet City Datum, which includes GSR Take Periods, the modeling consistently shows that the water surface elevation under the GSR Project is expected to be lower than the modeled existing conditions, but higher than the cumulative water surface elevation, while the water surface elevation under the SFGW project is expected to be significantly lower than any of the other model scenarios (see Figures 5.16-11 and 5.16-12). This suggests that the GSR Project's individual effects would ameliorate the project-specific effects of the SFGW project and that the GSR Project's contribution to the cumulative impact on water quality, fisheries, and fish-related beneficial uses would therefore not be cumulatively considerable (*less than significant*).

The Project's contribution to cumulative impacts is *less than significant*. Nevertheless, Mitigation Measures M-HY-9a (Lake Level Monitoring and Modeling for Lake Merced) and M-HY-9b (Lake Level Management for Lake Merced) require the SFPUC to implement lake level management procedures to address Project-specific impacts by maintaining Lake Merced at water levels similar to conditions that are predicted to occur without the Project. Implementation of this mitigation measure would therefore also serve to mitigate potential impacts on the fish habitat-related beneficial uses of Lake Merced by ensuring that adverse effects to water quality are avoided through lake level management. As a result, the contribution of the GSR Project to a *significant* cumulative impact relative to fish habitat would not be cumulatively considerable (*less than significant*).

Wetlands

Under the modeled cumulative condition, the water surface elevation of Lake Merced is predicted to fluctuate between -4.9 and 9.5 feet City Datum, with a mean of 6.1 feet (Kennedy/Jenks 2012). In addition, the water surface elevation is predicted to be between 6 and 9.5 feet City Datum (levels at which the extent of wetlands is predicted to increase such that there would be no net loss of wetlands) for about 65 percent of the time, and for periods of up to 19 to 26 months. For the remaining 35 percent of time, the water surface elevation of Lake Merced is predicted to be less than 6 feet City Datum, lasting for periods of up to 12 to 68 consecutive months. These durations would provide ample time to induce a loss of wetlands and their conversion to other habitat types. The GIS-based vegetation change analysis prepared for this EIR predicts losses, when compared to existing conditions, of up to 37 percent of wetland area (about 16 acres) at a lake surface elevation of 1 foot City Datum (Tables 5.14-14 and 5.14-15), much of which (about 10.5 acres) would be regained as water levels decline further to the cumulative predicted minimum of -4.9 feet City Datum. Therefore, wetland loss is also expected under the cumulative condition, but the losses would be less than those under modeled existing conditions, due to less frequent and shorter durations of inundation. Nonetheless, with implementation of the cumulative projects, water surface elevations would promote wetland loss for about 35 percent of the model period, and water surface elevations would promote wetland increases for about 65 percent of the model period. Therefore, over the model period, it is not expected that there would be a permanent cumulative loss of wetlands, and therefore the potential cumulative impact relative to loss of wetlands would be *less than significant*.

Wildlife nursery sites

As described in the modeled existing conditions impacts discussion, predicted rises in water surface elevations could result in a loss of rookery trees and other eucalyptus trees that provide potential alternate nesting substrate for herons and cormorants. Under the modeled cumulative scenario, the maximum water surface elevation is assumed not to exceed 9.5 feet City Datum, as discussed previously. The 2012 GIS-based vegetation change analysis conducted in support of this EIR predicts that about 10 percent of eucalyptus forest would be lost at a water surface elevation of 9 feet City Datum and 15 percent would be lost at 10 feet City Datum. Therefore, it is estimated that less than 15 percent would be lost at the maximum cumulative water surface elevation of 9.5 City Datum. While some rookery trees at North and South Lakes would be lost, ample eucalyptus forest would remain for nesting herons and cormorants to utilize. The most isolated stand of eucalyptus on East Lake would remain intact, with no expected loss of rookery trees due to water level rise. As shown in Table 5.14-17 (Predicted Loss of Eucalyptus Forest with Rising Water Levels) in the Impact BR-9 analysis, relative to predicted losses under modeled existing conditions, losses due to the cumulative projects would represent no more than an additional five percent loss of eucalyptus forest. Therefore, the cumulative impact on wildlife nursery sites would be *less than significant*.

5.15 GEOLOGY AND SOILS

The descriptions of geology, soils, and seismic hazards in this section rely on information gathered from the U.S. Geologic Survey (USGS), the Natural Resources Conservation Service ([NRCS]; previously known as the Soil Conservation Service), the California Geologic Survey (CGS), and three geotechnical investigations[1] prepared for the San Francisco Public Utilities Commission (SFPUC) by Geotechnical Consultants, Inc. for Sites 1, 4, 5, 6, 7, 8, 9, 10, 12, 13, 15, and 16 (Geotechnical Consultants 2009a, 2009b, 2012). These reports have been reviewed to determine relevant information for the EIR analysis and Project facility sites are evaluated for their potential to be affected by or to increase risks associated with identified geologic and seismic hazards. Appropriate mitigation measures are identified for impacts determined to be significant.

5.15.1 Setting

5.15.1.1 Regional Physiography

The Project would be located on the San Francisco Peninsula (Peninsula), which is part of the Coast Ranges Geomorphic Province (Coast Ranges). The topography of the Coast Ranges is characterized by northwest-southeast-trending mountain ridges and intervening valleys that have formed over millions of years due to movements of the earth's crust (referred to as tectonics). The bedrock underlying the Coast Ranges is referred to as the Franciscan Complex – a mixture of ancient seafloor sediments and volcanic rocks that have undergone alteration by heat and pressure deep within the earth. This rock unit forms most of the hills and mountains of the Peninsula. Overlying the Franciscan Complex bedrock are geologically young sedimentary deposits that are generally flat and underlie most of the urban core of the San Francisco Bay Area (Bay Area). Many of these basin deposits form when streams, bays, and estuaries deposit materials shed from surrounding hills and mountains. The mountains and hills of the San Francisco Peninsula are separated from the parallel range of the East Bay Hills by San Francisco Bay. The proposed facility sites on the Peninsula are located east of the San Andreas Fault Zone, along flatlands adjacent to San Francisco Bay.

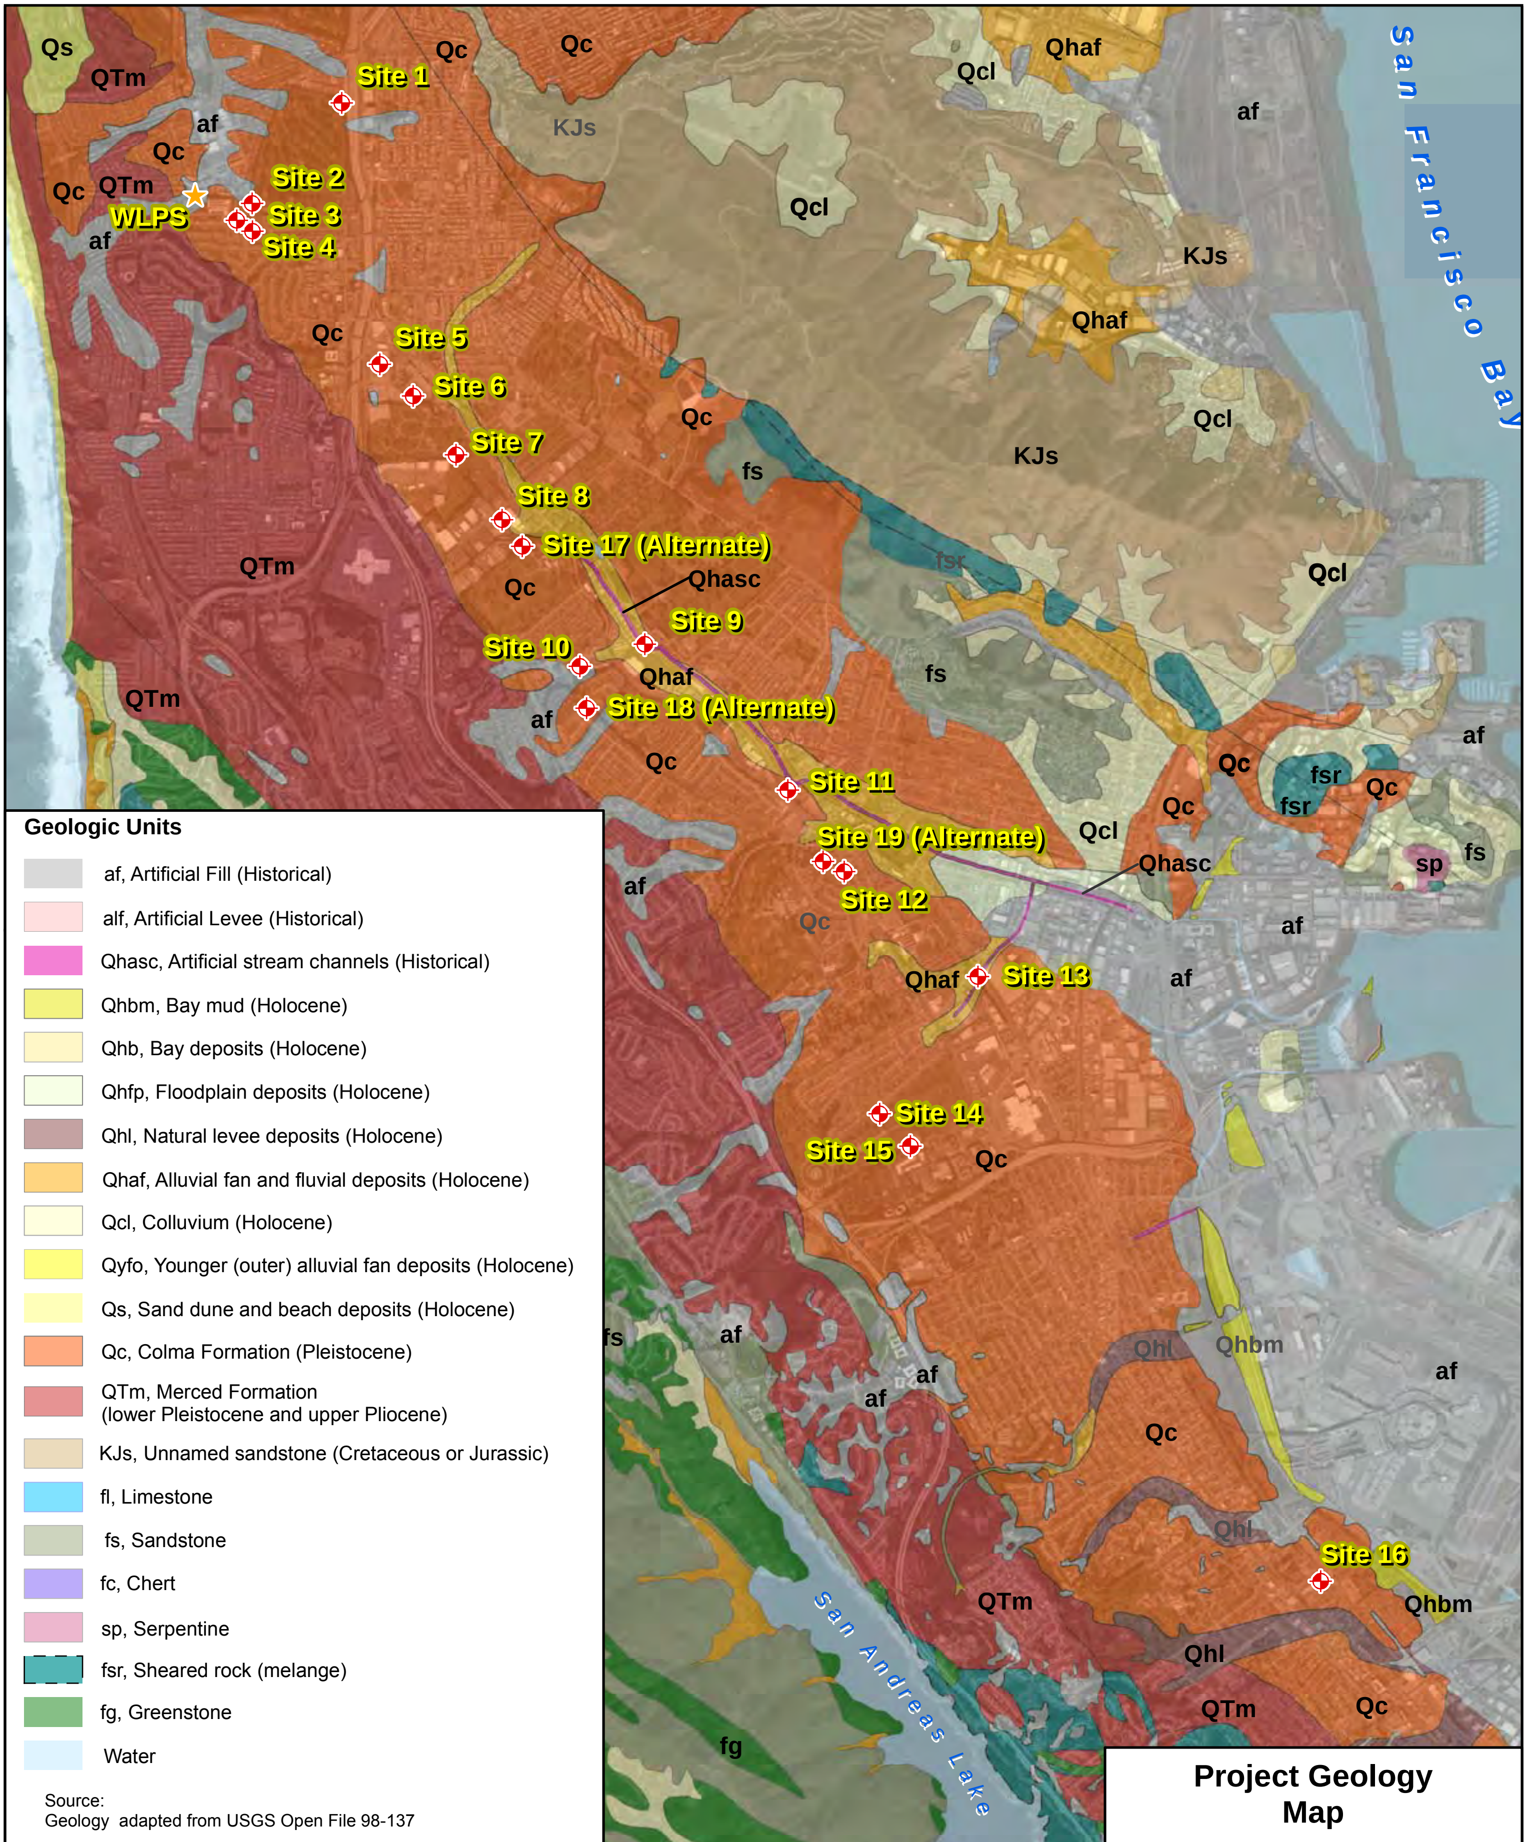
5.15.1.2 Project Area Geology

The geological setting of the Project area is based on information from two USGS geologic maps (USGS 1998a, 1998b) and the three geotechnical reports mentioned above (Geotechnical Consultants 2009a, 2009b, 2012).

---

[1] Due to the close proximity of sites, the information in the geotechnical investigation for Site 4 was used to characterize Sites 2 and 3; the information regarding Sites 8, 10, and 12 was used to characterize Sites 17 (Alternate), 18 (Alternate), and 19 (Alternate), respectively; and the information for Site 15 was used to characterize Site 14. Due to access issues, a geotechnical investigation has not yet been performed for Site 11. Regional geologic, liquefaction, and soil mapping was used to characterize Site 11. The SFPUC would conduct site specific investigations for alternate sites if they are chosen for construction (SFPUC 2012).

As shown on Figure 5.15-1 (Project Geology Map), the proposed facility sites would be located on flatlands underlain by Colma Formation, alluvium deposits, slope debris/ravine fill, natural levee deposits, and artificial fill. Table 5.15-1 (Geologic Units, Landslide, Liquefaction Susceptibility and Shaking Severity Levels at Facility Sites) lists the geologic units identified at each site where excavation or other ground disturbance would occur and the landslide and liquefaction susceptibilities of each unit. The Colma Formation consists predominantly of damp to moist, medium dense to very dense, silty sand, and poorly graded sand with silt. Artificial fill consists of damp to moist, loose to medium dense, silty sand, silty fine sand, and sandy silt. Natural levee deposits consist of damp to moist, loose to medium dense, poorly graded fine sand to silty fine sand (Geotechnical Consultants2009a, 2009b). The alluvium in the study area is mostly sand and silt, but locally contains clay, gravel, or boulders (USGS 1998a). Slope debris and ravine fill overlying the Colma Formation is typically silty to clayey sand, or gravel and unstratified or poorly stratified.



Geologic Units

- af, Artificial Fill (Historical)
- alf, Artificial Levee (Historical)
- Qhasc, Artificial stream channels (Historical)
- Qhbm, Bay mud (Holocene)
- Qhb, Bay deposits (Holocene)
- Qhfp, Floodplain deposits (Holocene)
- Qhl, Natural levee deposits (Holocene)
- Qhaf, Alluvial fan and fluvial deposits (Holocene)
- Qcl, Colluvium (Holocene)
- Qyfo, Younger (outer) alluvial fan deposits (Holocene)
- Qs, Sand dune and beach deposits (Holocene)
- Qc, Colma Formation (Pleistocene)
- QTm, Merced Formation (lower Pleistocene and upper Pliocene)
- KJs, Unnamed sandstone (Cretaceous or Jurassic)
- fl, Limestone
- fs, Sandstone
- fc, Chert
- sp, Serpentine
- fsr, Sheared rock (melange)
- fg, Greenstone
- Water

TABLE 5.15-1
Geologic Units, Landslide, Liquefaction Susceptibility and Shaking Severity Levels at Facility Sites

Site	Geologic Unit [(a)]	Landslide Area Type [(b)]	Liquefaction Susceptibility [(c)]	Shaking Severity Level [(d)]
Site 1	Colma Formation, artificial fill	flat land	low	violent
Site 2	Colma Formation, Slope debris and ravine fill	flat land	very low	violent
Site 3	Colma Formation, Slope debris and ravine fill	flat land	very low	violent
Site 4	Colma Formation, artificial fill	flat land	low	violent
Westlake Pump Station	Colma Formation, artificial fill	flat land	low	violent
Site 5	Colma Formation, artificial fill	flat land	low	violent
Site 6	Colma Formation, artificial fill	flat land	low	violent
Site 7	Colma Formation, artificial fill	flat land	low	violent
Site 8	Colma Formation, artificial fill, natural levee deposits	flat land	low	violent
Site 9	Colma Formation, artificial fill	flat land	low	violent
Site 10	Colma Formation, artificial fill, natural levee deposits	flat land	low	violent
Site 11	Colma Formation, Alluvium	flat land	very low, high[(e)]	violent
Site 12	Colma Formation, artificial fill	flat land	low	violent
Site 13	Colma Formation, artificial fill, natural levee deposits	flat land	low	violent
Site 14	Colma Formation	flat land	very low	violent
Site 15	Colma Formation, artificial fill	flat land	low	violent
Site 16	Colma Formation, artificial fill	flat land	low	violent
Site 17 (Alternate)	Colma Formation, Alluvium	flat land	very low, high[(e)]	violent
Site 18 (Alternate)	Colma Formation, artificial fill	flat land	very low, moderate	violent
Site 19 (Alternate)	Colma Formation	flat land	very low	violent

Notes:

(a) From Geotechnical Consultants 2009a, 2009b, 2012; USGS 1998a.

(b) From USGS 1997.

(c) Liquefaction susceptibility for Sites 1, 4, 5, 6, 7, 8, 9, 10, 12, 13, 15, and 16 is based on site-specific geotechnical data (Geotechnical Consultants 2009a, 2009b, 2012). Liquefaction susceptibility for Sites 2, 3, Westlake Pump Station, 11, 14, 17 (Alternate), 18 (Alternate), and 19 (Alternate) is based on regional liquefaction mapping (USGS 2006).

(d) Modified Mercalli Intensity Scale Value of IX (Violent) as modeled for 1906 Earthquake.

(e) USGS regional liquefaction mapping indicates liquefaction susceptibilities ranging from “very low” to “high” at Site 11 and Site 17 (Alternate).

5.15.1.3 *Geologic Hazards*

Slope Failure

Slope failures and landslides involve the downslope displacement and movement of material, either triggered by static (i.e., gravity) or dynamic (i.e., earthquake) forces. Exposed rock slopes undergo rockfalls, rockslides, or rock avalanches, while soil slopes experience soil slumps, rapid debris flows, and deep-seated rotational slides. Slope stability can depend on a number of complex variables, including the geology, soil structure, and amount of groundwater, as well as external processes such as climate, topography, slope geometry, and human activity. The factors that contribute to slope movements include those that decrease the resistance in the slope materials and those that increase the stresses on the slope. Landslides can occur on slopes of 15 percent or less, but the probability is greater on steeper slopes that exhibit old landslide features such as scarps[2], slanted vegetation, and transverse ridges[3]. Landslides typically occur within slide-prone geologic units that contain excessive amounts of water, are located on steep slopes, or where planes of weakness are parallel to the slope angle.

In 1998, USGS released a preliminary map and geographic information system (GIS) database that provides a summary of the distribution of landslides evident in the landscape of the San Francisco Bay region (USGS 1997). The map is a digitized nine-county compilation of existing landslides, including San Mateo County and encompassing the facility sites. The landslide area type for each well facility site where excavation or other ground disturbance would occur is summarized in Table 5.15-1 (Geologic Units, Landslide, Liquefaction Susceptibility and Shaking Severity Levels at Facility Sites). The proposed facility sites are located in areas mapped as flat land, which is defined as areas of gentle slope at low elevation that have little or no potential for the formation of slumps, transitional slides, or earth flows except along stream banks or terrace margins (USGS 1997).

Although all sites have been mapped as flat land by the USGS, geotechnical investigations, surveys, and field visits indicate that mild to moderate slopes exist at Sites 4, 6, 7, 17 (Alternate), and 18 (Alternate). The terrain at Site 4 is characterized as mildly sloping, generally less than seven percent slopes, along Park Plaza Drive, with an embankment (about 20-foot high) that descends on an approximately 30 percent slope from the proposed site to the Jefferson Elementary School playing field (Geotechnical Consultants 2012). Site 6 would be located on mildly sloping terrain generally less than 20 percent slopes (Geotechnical Consultants 2009b). Site 7 would be located on mildly sloping grassy terrain (Geotechnical Consultants 2009a). Although geotechnical investigations have not been performed for Sites 17 (Alternate) and 18 (Alternate), field visits indicate that the sites have moderate slopes that are slightly greater than 20 percent.

---

[2] A scarp is a cliff formed by faulting, erosion, or landslides.
[3] Transverse ridges are linear ridges within an existing landslide.

Naturally Occurring Asbestos

Asbestos is a common name for a group of naturally occurring fibrous silicate minerals that are made up of thin, but strong, durable fibers. Asbestos is a known carcinogen and presents a public health hazard if it is present in the friable (easily crumbled) form. The underlying geology of the facility sites consists primarily of the Colma Formation, with small pockets of alluvium, slope debris/ravine fill, and artificial fill. Franciscan ultramafic rock, including serpentine, is not mapped in the vicinity of the proposed facility sites (Geotechnical Consultants 2009a, 2009b, 2012; USGS 1998b). In addition, based on review of Open File Report 2000-19 (*A General Location Guide for Ultramafic Rocks in California - Areas More Likely to Contain Naturally Occurring Asbestos*), no ultramafic rock units occur in the areas of the facility sites (CDC 2000). The potential to encounter naturally occurring asbestos is further addressed in Section 5.17, Hazards and Hazardous Materials.

Soils

Soil surveys performed by the NRCS, in cooperation with the Regents of the University of California, provide information on surface and near-surface soil materials in the Project area. Table 5.15-2 (Soil Properties in the Project Area) lists each soil type identified at facility sites and is based on the *Soil Survey of San Mateo County, Eastern Part, and San Francisco County* (NRCS 1991).

Problematic soils, such as those that are expansive or corrosive, can damage structures and buried utilities and increase maintenance requirements. Expansive soils are characterized by their ability to undergo significant volume change (i.e., to shrink and swell) due to variations in moisture content. Changes in soil moisture can result from rainfall, landscape irrigation, utility leakage, roof drainage, and/or perched groundwater. Expansive soils are typically very fine grained and have a high to very high percentage of clay. Expansion and contraction of expansive soils in response to changes in moisture content can lead to differential and cyclical movements that can cause damage and/or distress to structures and equipment.

The corrosivity of soils is commonly related to several key parameters, including soil resistivity, the presence of chlorides and sulfates, oxygen content, and pH. Typically, the most corrosive soils are those with the lowest pH and highest concentration of chlorides and sulfates. Wet/dry conditions can result in a concentration of chlorides and sulfates, as well as movement in the soil, both of which tend to break down the protective corrosion films and coatings on the surfaces of building materials. High-sulfate soils are also corrosive to concrete and may prevent complete curing, reducing the strength of the concrete considerably. Low pH and/or low-resistivity soils can corrode buried or partially buried metal structures. Depending on the degree of corrosivity of the subsurface soils, building materials such as concrete, reinforcing steel in concrete structures and bare-metal structures exposed to these soils can deteriorate, eventually leading to structural failures.

Soil types identified include Orthents, which are soils that have been cut and filled for recreational or urban development, and Urban Land, which is covered by asphalt, concrete, buildings, or other structures.

TABLE 5.15-2
Soil Properties in the Project Area

Soil Unit	Runoff Class	Water Erosion	Shrink/Swell Potential
Orthents, cut and fill, 0-15 percent slope	Medium	Moderate	Low
Orthents, cut and fill-Urban land complex, 5-75 percent slopes	Medium to Very Rapid	Moderate to Very High	Low
Urban Land	Not applicable	Not applicable	Not applicable
Urban land-Orthents, smoothed complex, 5-50 percent slopes	Medium to Rapid	Moderate to High	Low

Source: NRCS 1991

The properties and characteristics of the soil types described above are highly variable because of the differences in the kind and amount of fill material used. These soils vary greatly in thickness and in the texture of the surface layer. Most of these soil units in the Project area are overlain by recreational development, cemeteries, and urban development land uses (NRCS 1991).

5.15.1.4 Regional Faulting and Seismic Hazards

Seismicity

The Bay Area is situated near the boundary between two major tectonic plates, the Pacific Plate to the southwest and the North American Plate to the northeast. Since the Miocene epoch (approximately 23 million years ago), about 200 miles of right-lateral slip has occurred along the San Andreas Fault Zone to accommodate the relative movement between these two plates. This movement has juxtaposed the granitic rocks southwest of the San Andreas Fault with the Franciscan Complex rocks lying to the northeast. The movement between the Pacific Plate and the North American Plate generally occurs across a 50-mile zone extending from the San Gregorio fault in the southwest to the Great Valley Thrust Belt to the northeast. In addition to the right-lateral slip movement between tectonic plates, a compressional component of relative movement has developed during the last 3.5 million years between the Pacific Plate and the Sierran micro-plate of the North American Plate at the latitude of San Francisco Bay.

Figure 5.15-2 (Regional Fault Map) shows the locations of active[4] and potentially active[5] faults in the San Francisco Bay region. The San Andreas, San Gregorio, Hayward, Rodgers Creek, Calaveras, and Greenville strike-slip faults[6] are active faults of the San Andreas system that predominantly

[4] An active fault is one that shows geologic evidence of movement within Holocene time (approximately the last 11,000 years).
[5] A potentially active fault is one that shows geologic evidence of movement during the Quaternary period (approximately the last 1.6 million years).
[6] Strike-slip faults involve the two blocks moving parallel to each other without a vertical component of movement.

accommodate lateral movement between the North American and Pacific tectonic plates. Active blind- and reverse-thrust faults[7] in the San Francisco Bay region that accommodate compressional movement include the Monte Vista-Shannon and Mount Diablo faults. The San Andreas Fault is the nearest active fault, located 1.2 to 2.3 miles from the various proposed facility sites (CDC 1982a, 1982b).

The USGS estimates that there is a 63 percent probability of a strong earthquake (magnitude 6.7 or higher on the Richter Magnitude Scale) occurring on one of the regional faults in the 30-year period between 2007 and 2036, with a 21 percent chance of such an earthquake occurring on the northern San Andreas fault, the closest fault to the proposed Project (USGS 2008). Strong groundshaking and other earthquake-related phenomena could occur at facility sites due to a major earthquake on the San Andreas fault or one of the other regional faults, including the Hayward and Calaveras faults – each of which parallels the San Andreas fault and is capable of generating large (greater than magnitude 6.7) earthquakes.

Fault Rupture

Surface rupture occurs when movement on a fault deep within the earth breaks through to the surface. Surface ruptures associated with the 1906 San Francisco earthquake extended for more than 260 miles, with displacements of up to 21 feet. However, not all earthquakes result in surface rupture. The Loma Prieta earthquake of 1989 caused major damage in the Bay Area, but the fault movement did not break through to the ground surface.

Fault rupture almost always follows pre-existing faults, which are zones of weakness. Rupture may occur suddenly during an earthquake or slowly in the form of fault creep. Sudden displacements are more damaging to structures because they can suddenly displace structures and are accompanied by shaking. Fault creep is the slow rupture of the earth's crust. In developed areas, fault creep can offset and deform curbs, streets, buildings, and other structures that lie on the fault trace. Active fault traces do not cross facility sites (Geotechnical Consultants 2009a, 2009b, 2012; CDC 1982a, 1982b).

Groundshaking

The intensity of the seismic shaking, or strong ground motion, during an earthquake is dependent on the distance between the Project area and the epicenter of the earthquake, the magnitude of the earthquake, and the geologic conditions underlying and surrounding the Project area. Earthquakes occurring on faults closest to the Project area would most likely generate the largest ground motions.

The intensity of earthquake-induced ground motions and the potential forces affecting structures within the Project area can be described using peak ground accelerations, which are represented as a fraction of

[7] A reverse fault is one with predominantly vertical movement in which the upper block moves upward in relation to the lower block; a thrust fault is a low-angle reverse fault. Blind-thrust faults are low-angled subterranean faults that have no surface expression.

Regional Groundwater Storage and Recovery Project

Figure 5.15-2

Source: CA Dept. of Conservation, CGS 2005 the acceleration of gravity (g).[8] The CGS estimates the peak ground accelerations for the 10 percent probability of exceedance in 50 years (475-year return period) at 0.67g to 0.69g (USGS 2008).

Liquefaction

Liquefaction is a phenomenon in which saturated granular sediments temporarily lose their shear strength during periods of earthquake-induced, strong groundshaking. The susceptibility of a site to liquefaction is a function of the depth, density, and water content of the granular sediments and the magnitude of earthquakes likely to affect the site. Saturated, unconsolidated silts, sands, silty sands, and gravels within 50 feet of the ground surface are most susceptible to liquefaction. Liquefaction-related phenomena include vertical settlement from densification, lateral spreading, ground oscillation, flow failures, loss of bearing strength, subsidence, and buoyancy effects.

The USGS classifies liquefaction susceptibility into five categories that describe: the likely proportion of all liquefaction occurrences that could take place in each category; the abundance or frequency of liquefaction occurrence within the category; the strength of shaking required to produce liquefaction; and the Quaternary-age geologic units included (USGS 2006). The five categories are described as follows:

- **Very High.** The USGS estimates that about 40 to 50 percent of future liquefaction effects would occur within geologic units assigned this category. Only modest groundshaking (peak ground acceleration of about 0.1g) would be required to cause liquefaction. Geologic map units that fall within this category include the latest Holocene and historical stream channel deposits, as well as artificial fills over bay and other estuarine mud.
- **High.** The USGS estimates that about 20 to 30 percent of future liquefaction effects would occur within geologic units assigned this category. Relatively modest groundshaking (peak ground acceleration of about 0.1g to 0.2g) would be required to cause liquefaction. Geologic map units within this category include the latest Holocene and historical alluvium, natural levees, and stream terraces.
- **Moderate.** The USGS estimates that about 20 to 30 percent of future liquefaction effects would occur within geologic units assigned this category. Somewhat stronger groundshaking (greater than peak ground acceleration of about 0.1g to 0.2g) would be required to cause liquefaction. Geologic map units within in this category include the latest Pleistocene and Holocene bay and other estuarine mud, alluvial fan and levee deposits, and stream terrace deposits.
- **Low.** The USGS estimates that about two percent of future liquefaction effects would occur within geologic units assigned this category. Stronger groundshaking (peak ground acceleration of about 0.5g) would be required to cause liquefaction. Geologic map units within in this category include the basin deposits, various late Pleistocene deposits and Pleistocene marine terrace deposits.

---

[8] Acceleration of gravity (g) = 980 centimeters per second squared. 1.0g of acceleration is a rate of increase in speed equivalent to a car traveling 328 feet from rest in 4.5 seconds.

- **Very Low.** The USGS estimates that about two percent of future liquefaction effects would occur within geologic units assigned this category. Stronger groundshaking (greater than peak ground acceleration of about 0.6g) would be required to cause liquefaction. Geologic map units within in this category include Pleistocene deposits, pre-Quaternary deposits and bedrock.

The liquefaction susceptibility at each facility site requiring excavation or other ground disturbance is shown in Table 5.15-1 (Geologic Units, Landslide, Liquefaction Susceptibility and Shaking Severity Levels at Facility Sites). In general, liquefaction susceptibility levels are low because of the generally dense and clayey nature of the Colma Formation and the depth to groundwater at the sites. However, USGS regional liquefaction mapping indicates moderate to high liquefaction susceptibility at portions of some sites (USGS 2006). Because the USGS mapping has a regional focus, the mapping only generally correlates with areas of known liquefaction hazard. The site-specific data generated from on-site geotechnical borings are considered to be more indicative of liquefaction potential and, therefore, are used instead of the USGS mapping to characterize most of the sites (Geotechnical Consultants 2009a, 2009b, 2012). The aforementioned USGS regional mapping indicates a high liquefaction potential – and geotechnical investigations have not been performed – for portions of Sites 11, 17 (Alternate), and 18 (Alternate). However, these three well facility sites are located in proximity to sites for which geotechnical investigations have been performed (Sites 12, 8, and 10, respectively) and for which site-specific data indicate a low liquefaction susceptibility (Geotechnical Consultants 2009a, 2009b, 2012). Sites 11, 17 (Alternate), and 18 (Alternate) would be located close to, and within, similar geologic units and groundwater conditions as, Sites 12, 8, and 10, respectively; therefore, the liquefaction susceptibility levels at these sites are characterized as low.

Lateral Spreading

Of the liquefaction hazards, lateral spreading generally causes the most damage. Lateral spreading refers to landslides that commonly form on gentle slopes and that have rapid fluid-like flow movement, like water (USGS 2012). During lateral spreading, a mass moves toward an unconfined area, such as a descending slope or stream-cut bluff, and can occur on slope gradients as gentle as one degree. Drainages and swales between hill slopes are generally filled by alluvium[9], colluvium, landslide debris, and slope wash. Unconsolidated deposits often develop soils along steep and shallow slopes in these areas. Well facility Sites 17 (Alternate) and 18 (Alternate) have moderate slopes and are mapped by USGS as having moderate to high liquefaction susceptibility (USGS 2006). These characteristics could potentially make facilities at Sites 17 (Alternate) and 18 (Alternate) susceptible to lateral spreading. However, as described in the previous section on liquefaction, these sites are located in proximity to sites for which geotechnical investigations have been performed (Sites 8 and 10) and for which site-specific data indicate low liquefaction susceptibility (Geotechnical Consultants 2009a, 2009b, 2012). Sites 17 (Alternate) and 18 (Alternate) would be located close by, and within, similar geologic units with groundwater conditions similar to Sites 8 and 10, respectively. Therefore, the liquefaction and associated lateral spreading

[9] Alluvium consists of unconsolidated mixtures of gravel, sand, clay, and silt typically deposited by streams.

susceptibility levels at these sites are characterized as low, consistent with the classification for Sites 8 and 10 in the geotechnical reports prepared by Geotechnical Consultants, Inc.

Earthquake-induced Settlement

Settlement of the ground surface can be accelerated and accentuated by earthquakes. During an earthquake, settlement can occur as a result of the relatively rapid rearrangement, compaction, and settling of subsurface materials (particularly loose, non-compacted, and variable sandy sediments). Settlement can occur both uniformly and differentially (i.e., where adjoining areas settle at different rates). Areas are susceptible to differential settlement if underlain by compressible sediments, such as poorly engineered artificial fill or bay mud. Facility sites with underlying artificial fills and other potentially unstable soils with a moderately high hazard from seismically induced settlement include Sites 1, 5, 8, 12, 13, 14, 15, and 16 (Geotechnical Consultants 2009a, 2009b, 2012). Sites 17 (Alternate) and 18 (Alternate) are close to, and within, similar geologic units and groundwater conditions as Sites 8 and 10, respectively. Therefore, this analysis assumes that hazards from earthquake-induced settlement may be moderately high at these sites, as well.

Seismic Slope Instability/Ground Cracking

Earthquake motion can also induce substantial stresses in slopes, causing earthquake-induced landslides or ground cracking when the slope fails. Earthquake-induced landslides can occur in areas with steep slopes that are susceptible to strong ground motion during an earthquake. The 1989 Loma Prieta earthquake triggered thousands of landslides over an area of 770 square miles. Well facility sites with moderate slopes that could potentially be susceptible to seismic slope instability include Sites 2, 4, 6, and 7 (Geotechnical Consultants 2009a, 2009b, 2012). Sites 17 (Alternate) and 18 (Alternate) also have moderate slopes. Therefore, this analysis assumes that Sites 17 (Alternate) and 18 (Alternate) may be susceptible to seismic slope instability.

5.15.2 Regulatory Framework

5.15.2.1 Federal

No federal regulations are associated with geology, soils, and seismicity for the proposed Project.

5.15.2.2 State

Alquist-Priolo Earthquake Fault Zoning Act

The Alquist-Priolo Earthquake Fault Zoning Act was passed in 1972 to mitigate the hazard of surface faulting to structures for human occupancy. In accordance with this act, the State Geologist established regulatory zones, called “earthquake fault zones,” around the surface traces of active faults and published maps showing these zones. Within these zones, buildings for human occupancy cannot be constructed across the surface trace of active faults. Because many active faults are complex and consist of more than one branch, each earthquake fault zone extends approximately 200 to 500 feet on either side of the mapped fault trace.

Title 14 of the California Code of Regulations (CCR), Section 3601(e), defines buildings intended for human occupancy as those that would be inhabited for more than 2,000 hours per year. The proposed Project does not cross an Alquist-Priolo Earthquake Fault Zone (Figure 5.15-2 [Regional Fault Map]) and does not include buildings that meet this criterion for human occupancy. Therefore, these provisions of the act do not apply to the Project.

Seismic Hazards Mapping Act

Like the Alquist-Priolo Act, the Seismic Hazards Mapping Act of 1990 (Public Resources Code [PRC] Sections 2690 to 2699.6) is intended to reduce damage resulting from earthquakes. While the Alquist-Priolo Act addresses surface fault rupture, the Seismic Hazards Mapping Act addresses other earthquake-related hazards, including strong groundshaking, liquefaction and seismically induced landslides. Its provisions are similar in concept to those of the Alquist-Priolo Act: the State is charged with identifying and mapping areas at risk of strong groundshaking, liquefaction, landslides, and other corollary hazards, with cities and counties required to regulate development within mapped Seismic Hazard Zones.

Under the Seismic Hazards Mapping Act, permit review is the primary mechanism for local regulation of development. Specifically, cities and counties are prohibited from issuing development permits for sites within Seismic Hazard Zones until appropriate site-specific geologic and/or geotechnical investigations have been conducted and measures to reduce potential damage have been incorporated into the development plans. The Seismic Hazard Maps released for San Mateo County include liquefaction and landslides maps covering the southeastern portion of the County. The Seismic Hazard Maps for the San Francisco South and Montara Mountain USGS quadrangles, which cover the Project area, are under development and have not been published by the CGS.

Building Codes

The California Building Code (CBC), which is codified in CCR Title 24, Part 2, was promulgated to safeguard the public health, safety, and general welfare by establishing minimum standards related to structural strength, egress facilities, and general building stability. The purpose of the CBC is to regulate and control the design, construction, quality of materials, use/occupancy, location, and maintenance of all building and structures within its jurisdiction. Title 24 is administered by the California Building Standards Commission, which, by law, is responsible for coordinating all building standards. The 2007 CBC is based on the 2006 International Building Code (IBC) published by the International Code Conference. In addition, the CBC contains necessary California amendments that are based on the American Society of Civil Engineers (ASCE) Minimum Design Standards 7-05. ASCE 7-05 provides requirements for general structural design and includes means for determining earthquake loads, as well as other loads (e.g., flood, snow, wind) for inclusion in building codes. The provisions of the CBC apply to the construction, alteration, movement, replacement, and demolition of every building or structure or any appurtenances connected or attached to such buildings or structures throughout California.

The earthquake design requirements take into account the occupancy category of the structure, site class, soil classifications, and various seismic coefficients, all of which are used to determine a Seismic Design Category (SDC) for a project. The SDC is a classification system that combines the occupancy categories with the level of expected ground motions at the site and ranges from SDC A (very small seismic vulnerability) to SDC E/F (very high seismic vulnerability and near a major fault). Design specifications are then determined according to the SDC.

5.15.2.3 Local

SFPUC General Seismic Design Requirements

The SFPUC established the General Seismic Design Requirements (SFPUC 2009) to implement consistent criteria for the design and retrofit of all facilities and components of the regional water system. These design requirements require that every Water System Improvement Program (WSIP) project must have project-specific design criteria based on the local seismic environment and the importance of the subject facility to achieve the water service delivery goals in the event of a major earthquake. A major earthquake is identified in the General Seismic Design Requirements as earthquakes of M 7.8 or larger on the San Andreas Fault, M 7.1 or larger on the Hayward Fault, or M 6.8 or larger on the Calaveras Fault. The design criteria are based on standard industry practices, codes and standards, but exceed these requirements for facilities that are located in a severe seismic environment and are needed to achieve water system delivery goals. Under these design requirements, each facility is evaluated for its necessity in meeting the water service delivery goals and assigned a seismic performance class for the purposes of determining appropriate seismic design criteria. As described in Chapter 3, Project Description, Section 3.4.2.2 (Well Facility Types), the SFPUC has classified the proposed facilities as "Important" (Class II), which is defined as facilities that may experience damage, but should be capable of restoration to service within 30 days.

5.15.3 Impacts and Mitigation Measures

5.15.3.1 Significance Criteria

For the purposes of this EIR, the Regional Groundwater Storage and Recovery Project would have a significant effect related to geology, soils, and seismicity if it were to:

- Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:
    - Rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault (Refer to Division of Mines and Geology Special Publication 42).
    - Strong seismic ground shaking.
    - Seismic-related ground failure, including liquefaction.
    - Landslides.

- Result in substantial soil erosion or the loss of topsoil.
- Be located on a geologic unit or soil that is unstable, or that would become unstable as a result of the Project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction, or collapse.
- Be located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code, creating substantial risks to life or property.
- Have soils incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems where sewers are not available for the disposal of wastewater.
- Change substantially the topography or any unique geologic or physical features of the site.

5.15.3.2 Approach to Analysis

The potential for impacts related to geology, soils, and seismicity are evaluated according to the significance criteria listed above. Regional and local geologic maps and reports, as well as Project-specific geologic and geotechnical reports, were reviewed to identify geologic conditions and geologic hazards in the study area that, because of their proximity, could be directly or indirectly affected by the proposed Project or could affect the Project.

Area of No Project Impact

The following four significance criteria will not be discussed further in this section for the following reasons:

Expose people or structures to substantial adverse effects related to the risk of property loss, injury, or death due to fault rupture, seismic groundshaking, or landslides. This significance criterion is intended to address facility siting and design impacts and does not apply to temporary construction impacts. Therefore, this significance criterion is not applicable to Project construction activities and is only discussed below as it relates to potential long-term operational impacts.

Result in substantial soil erosion or the loss of topsoil. The proposed well facility sites have been highly altered from their original, natural state. As a result, the depth and amount of grading and excavation proposed by the SFPUC (see Table 3-10, Construction Soil Material Haul Amounts and Anticipated Haul Truck Trips) would result in little disturbance to native soils[10]. In addition, the proposed sites are near areas of moderate to intense urban uses, such as surface streets, schools, single- or multi-family residences, recreational, commercial, and industrial facilities, and the sites are not located in areas supporting agricultural uses. Consequently, no substantial loss of topsoil due to erosion or grading is anticipated during construction or operation of the Project.

[10] Site excavation and grading would be minor, with grading to a maximum depth of five feet for the building foundation (if the well facility is intended to have a building) and utilities underneath the building (see Chapter 3, Project Description, Section 3.5.1.2 [Construction of Well Facilities]); whereas, in general, pipeline trenches would be excavated to a depth of up to six feet and would be approximately 10 feet wide (see Chapter 3, Project Description, Section 3.5.1.3 [Water Distribution and Utility Pipeline Installation]).

Therefore, this significance criterion is not discussed further in this section. In addition, there would be no loss of topsoil or accelerated erosion during well operations given that the disturbed areas around the well facility would be restored to the general pre-construction conditions, and disturbed areas would be hydroseeded and receive erosion control measures as necessary (see Chapter 3, Project Description, Section 3.5.1.1 [Construction Methods for Production Wells]). Nevertheless, potential construction and operation impacts on water quality associated with soil erosion are addressed in Section 5.16, Hydrology and Water Quality.

Be located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code, creating substantial risks to life or property. This significance criterion is intended to address facility siting and design impacts; it does not apply to temporary construction impacts. Therefore, this significance criterion is not applicable to Project construction activities and is only evaluated as it relates to potential long-term operational impacts.

Have soils incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems. Project facility sites would be connected to municipal sewer systems and would not involve the construction or use of septic tanks or alternative wastewater disposal system. Therefore, the criterion related to capability of soils to support septic tanks or alternative wastewater disposal systems is not applicable to construction or operation of the Project.

Change the topography or any unique geologic or physical features of the site(s). Operation of the well facilities would not change the topography or impact geologic features given that the wells and buildings would be in place and no additional ground disturbance would occur during project operations. Therefore, this significance criterion is not applicable to long-term operational impacts and is only discussed below as it relates to Project construction activities.

The evaluation of potential geology and soil impacts in this section relies on information gathered from geotechnical investigations prepared specifically for the proposed Project, as well on published geologic hazard maps and site visits. As stated above, three geotechnical investigations were performed for Sites 1, 4, 5, 6, 7, 8, 9, 10, 12, 13, 15, and 16 (Geotechnical Consultants 2009a, 2009b, 2012). For the purposes of this analysis, the information in the geotechnical investigations for Site 4 was used to characterize the conditions at Sites 2 and 3 because these sites are located in close proximity to one another. The information in the geotechnical reports for Sites 8, 10, and 12 were used to characterize conditions at Sites 17 (Alternate), 18 (Alternate), and 19 (Alternate), and information for Site 15 was used to characterize conditions at Site 14 for the purpose of this analysis. Due to access issues, a geotechnical investigation has not yet been performed for Site 11. Regional geologic, liquefaction, and soil mapping was used to characterize Site 11.

5.15.3.3 Impact Summary

For the remaining significance criteria, specific impact analyses below are divided into two subsections: (1) construction impacts (short-term or temporary) and (2) operational impacts (long-term or permanent). Table 5.15-3 (Summary of Impacts – Geology and Soils) provides a summary of geology and soils impacts from the Project.

TABLE 5.15-3

Notes:

NI = No Impact
LS = Less than Significant
LSM = Less than Significant with Mitigation

5.15.3.4 Construction Impacts and Mitigation Measures

Impact GE-1: The Project would not be located on a geologic unit or soil that is unstable, or that would become unstable during construction. (Less than Significant)

The evaluation of impacts that follows discusses sites with no impacts first, followed by sites with less-than-significant impacts.

<u>Sites 1, 2, 3, 5, 8, 9, 10, 11, 12, 13, 14, 15, 16, 19 (Alternate), and the Westlake Pump Station</u>

Natural or constructed slopes could become destabilized during construction-related excavation and/or grading operations. Excavations for new pipelines, access roads, and well facilities could result in slope instability, potentially triggering slope failures that could result in landslides, slumps, soil creep, or debris flows. Slope failures are more likely to occur in areas with a history of previous failure and in weak geologic units exposed on unfavorable slopes, such as those areas mapped by the USGS as "few landslides," "many landslides," or "mostly landslides" (USGS 1997). As shown in Table 5.15-1 (Geologic Units, Landslide, Liquefaction Susceptibility and Shaking Severity Levels at Facility Sites), however, none of the proposed locations of the facility sites are mapped as being within these landslide area types.

Sites 1, 2, 3, 5, 9, 10, 11, 12, 13, 14, 15, 16, 19 (Alternate), and Westlake Pump Station would be located in relatively flat areas, which, accordingly, are not subject to slope failures (USGS 1997; Geotechnical Consultants 2009a, 2009b, 2012). Therefore, *no impact* would occur related to unstable soils at these sites.

Site 8 is also located in a flat area, and an elevated automobile dealership parking lot to the west that is at a higher elevation is not likely to pose landslide hazards to Site 8 because of an existing concrete retaining structure that would not be impacted and because Site 8 would have a 30 to 40-foot setback distance between the retaining wall and the proposed station building. Therefore, *no impact* would occur related to unstable soils at Site 8.

Impact Conclusion: No Impact

<u>Sites 4, 6, 7, 17 (Alternate), and 18 (Alternate)</u>

As described in Section 5.15.1.3, Geologic Hazards, geotechnical investigations and field visits indicate that mild (20 percent slopes or less) to moderate (greater than 20 percent slops but less than 30 percent slopes) slopes exist at Sites 4, 6, 7, 17 (Alternate), and 18 (Alternate). The potential for slopes at these sites to become destabilized during construction is considered unlikely due to the mapped and documented presence of generally dense granular materials, the absence of shallow groundwater, and the presence of vegetation that provides additional strengthening of the near surface soils (Geotechnical Consultants 2009a, 2009b, 2012; USGS 1998b). Therefore, impacts related to unstable soils would be *less than significant* at these sites.

Impact Conclusion: Less than Significant

Impact GE-2: The Project would not substantially change the topography or any unique geologic or physical features of the site(s). (Less than Significant)

Unique Geologic or Physical Features

All Sites

The proposed Project would include grading to construct new access driveways, pipeline connections, staging areas and facility buildings. None of the facility sites include rock outcrops or unique geologic or physical features. As a result, *no impact* would occur to unique geologic or physical features at the sites.

Impact Conclusion: No Impact

Topography

All Sites

Sites 1, 3, 5, 8, 9, 10, 11, 12, 13, 14, 15, 16, 19 (Alternate), and Westlake Pump Station would be located on flat land; the Project would not cause a substantial change to the topography of the sites. Sites 2, 4, 6, 7, 17 (Alternate), and 18 (Alternate) are in areas of mildly to moderately sloping terrain. Project grading would not substantially alter the topography of the sites. Site excavation and grading for construction of well facilities would be minor, with grading to a maximum depth of five feet for the building foundation (if the well facility is intended to have a building) and utilities underneath the building (see Chapter 3, Project Description, Section 3.5.1.2, [Construction of Well Facilities]). As a result, impacts related to a substantial change in existing topography would be *less than significant* for all sites.

Impact Conclusion: Less than Significant

5.15.3.5 Operation Impacts and Mitigations

Impact GE-3: The Project would expose people or structures to substantial adverse effects related to the risk of property loss, injury, or death due to fault rupture, seismic groundshaking, or landslides. (Less than Significant with Mitigation)

Fault Rupture

All Sites

Figure 5.15-2 (Regional Fault Map) shows the locations of active and potentially active faults in the San Francisco Bay region. The Serra Fault is the nearest active fault in the Project area, located approximately 0.25 to one mile from the various proposed well facilities. The San Andreas Fault Zone is located approximately 1.2 to 2.3 miles from the various proposed well facilities. The facility sites, including pipelines, would not be located within the San Andreas Fault Zone and no other active or potentially active faults are known to cross the sites (CDC 1982a, 1982b; Geotechnical Consultants 2009a, 2009b, 2012). Therefore, geologic impacts on people or structures related to surface fault rupture would be *less than significant.*

Impact Conclusion: Less than Significant

Groundshaking

<u>All Sites</u>

Groundshaking during an earthquake in the Project area is expected to be quite strong (i.e., greater than peak ground acceleration of approximately 0.7 to 0.9g per Geotechnical Consultants, Inc. 2009a, 2009b, 2012), which could result in disruption of water service or cause damage to well facility buildings or the Westlake Pump Station building. The potential for damage and subsequent disruption of water service from strong seismic ground shaking could therefore result in a *significant* impact.

The SFPUC's General Seismic Requirements for Design of New Facilities and Upgrade of Existing Facilities set forth criteria for the seismic design of facilities and components of WSIP facility improvement projects (SFPUC 2009). Under these design requirements, each facility is evaluated for its necessity in meeting the water service delivery goals and assigned a seismic performance class for the purpose of determining appropriate seismic design criteria. The SFPUC has classified the proposed facilities as "Important" (Class II), which is defined as facilities that may experience damage, but should be capable of restoration to service within 30 days (SFPUC 2009) (see Chapter 3, Project Description, Section 3.4.2.2 [Well Facility Types, Seismic Design Requirements]). The SFPUC requirements for ground shaking include specific design ground motion parameters and design spectra for engineering analysis and structure design.

Site-specific design criteria for sites with well facility buildings are provided in the site-specific geotechnical studies prepared for Sites 1, 4, 5, 6, 7, 8, 9, 10, 12, 13, 15, and 16 (Geotechnical Consultants 2009a, 2009b, 2012). Sites 2, 3, 14, 17 (Alternate), 19 (Alternate), and the Westlake Pump Station are adjacent to or very close to sites where a site-specific geotechnical study has been prepared, and where the design criteria for the adjacent site appear to be applicable. Mitigation Measure M-GE-3 (Conduct Site-Specific Geotechnical Investigations and Implement Recommendations) would reduce the impact of seismic ground shaking, as well as settlement (see Impact GE-4), on well facilities by requiring facilities to be designed and constructed in conformance with specific recommendations contained in design-level geotechnical studies, such as site-specific seismic design parameters and lateral earth pressures, use of engineered fill, and subgrade preparations for foundations systems and floor slabs. These measures are described in more detail in Mitigation measure M-GE-3 below. Therefore, with implementation of these measures, geologic impacts on people or structures related to seismic groundshaking following mitigation would be *less than significant*.

Mitigation Measure M-GE-3: Conduct Site-Specific Geotechnical Investigations and Implement Recommendations (All Sites)

The SFPUC shall conduct a site-specific design-level geotechnical study at Site 11 to provide recommendations for protection from property loss, injury, or death from ground shaking or settlement. Similarly, if Site 18 (Alternate) is selected, the SFPUC shall conduct a site-specific design-level geotechnical study for the site.

At all sites, the facilities shall be designed and constructed in conformance with the specific recommendations contained in design-level geotechnical studies. The recommendations made in the geotechnical studies shall be incorporated into the final plans and specifications and implemented during construction The site-specific recommendations in the design-level geotechnical studies relative to ground shaking include the following measures:

- Site-specific seismic design parameters in accordance with the International Building Code Static Force Procedure;
- Specified lateral earth pressures and seismic loading for retaining walls;
- Earthwork recommendations for site preparation, excavations, use of engineered fill and utility trench/pipe backfill; and
- Foundation recommendations for subgrade preparation, foundations systems, and floor slabs.

Site-specific recommendations in the design-level geotechnical studies relative to settlement include the following measures:

- Supporting structures at these sites on structurally rigid mat foundations with contact pressures in accordance with the bearing capacities identified in the geotechnical reports;
- Post-tensioning to reinforce and increase the structural rigidity of grade beams and shallow footings;
- Over-excavating artificial fill materials and loose granular soils and recompaction with moisture treated engineered fill to develop a mass of densified soil beneath the proposed well buildings; and
- Using flexible pipe connections to accommodate dynamic settlements due to seismic loading.

Impact Conclusion: Less than Significant with Mitigation

Seismically-induced Landslides

<u>All Sites</u>

As described under Impact GE-2, the facility sites would be located in areas mapped as flat land (USGS 1998a). However, geotechnical investigations, surveys, and field visits have indicated that mild to moderate slopes exist at Sites 4, 6, and 7. Although no site specific geotechnical reports exist for Sites 17 (Alternate) and 18 (Alternate), mapping shows these sites are underlain by the same geologic units as nearby well facilities, and similar groundwater levels would be expected given the close proximity to other wells for which geotechnical data is available (see Section 5.15.1.3, Geologic Hazards). The potential for seismically induced landslides is considered unlikely at the sites due to the presence of generally dense granular materials and the absence of shallow groundwater (Geotechnical Consultants 2009a, 2009b, 2012; USGS 1998b). At Site 4, roots from vegetation and trees provide additional strengthening of the near surface soil mass (Geotechnical Consultants 2012). Therefore, geologic impacts on people or structures related to seismically induced landslides or slope failures would be *less than significant* for all sites.

Impact Conclusion: Less than Significant

Impact GE-4: The Project would be located on a geologic unit or soil that is unstable, or that would become unstable. (Less than Significant with Mitigation)

Liquefaction

All Sites

Liquefaction-related phenomena can include lateral spreading, ground oscillation, loss of bearing strength, subsidence, and buoyancy effects, all of which could damage the proposed well facilities and associated pipelines. Seismically induced settlement can occur in areas underlain by compressible sediments, which can cause damage to structures when settlement does not occur evenly across the footprint of a structure, resulting in differential settlement. Stream channel deposits and recent valley alluvium are generally the most susceptible to earthquake-induced settlement. Additionally, artificial fills, especially fills placed before 1965 and those placed on top of bay mud, are highly susceptible to mobilization and densification, resulting in earthquake-induced subsidence. The liquefaction susceptibility for each site is summarized in Table 5.15-1 (Geologic Units, Landslide, Liquefaction Susceptibility and Shaking Severity Levels at Facility Sites).

Sites 1, 2, 3, 4, 5, 6, 7, 11 (not including the sanitary sewer pipeline), 12, 14, 15, 16, 19 (Alternate), and the Westlake Pump Station would be located in areas mapped by the USGS as having very low to low liquefaction susceptibility (USGS 2006). In addition, the site-specific data from geotechnical borings for Sites 1, 4, 5, 6, 7, 12, 15, and 16 indicate that these sites would not be susceptible to liquefaction because of the generally dense and clayey nature of the Colma formation (Geotechnical Consultants 2009a, 2009b, 2012). Therefore, potential geologic impacts on people or structures related to liquefaction would be *less than significant* for these sites.

Sites 9, 13, and 18 (Alternate) would be located in areas mapped by the USGS as having moderate liquefaction susceptibility associated with artificial fill and alluvial deposits of Colma Creek (USGS 2006). However, the site-specific data from the geotechnical borings at Sites 9 and 13 indicate that these sites would not be susceptible to liquefaction due to the generally dense and clayey nature of the Colma Formation at the sites (Geotechnical Consultants 2009a, 2009b). In addition, and as shown on Figure 5.15-1 (Project Geology Map), the Colma formation also underlies Site 18 (Alternate). Due to the dense and clayey nature of the Colma formation, this site would also not be susceptible to liquefaction. Therefore, potential geologic impacts on people or structures related to liquefaction would be *less than significant* for these sites.

Sites 8, 10, and 17 (Alternate) would be located in an area mapped by the USGS as having high liquefaction susceptibility associated with alluvial deposits of Colma Creek (USGS 2006). In addition, a portion of the proposed sanitary sewer connection at Site 11 would be located in an area mapped as having high liquefaction susceptibility. However, the site-specific data from the geotechnical borings at Sites 8 and 10 indicate that these sites would not be susceptible to liquefaction due to the generally dense and clayey nature of the Colma formation, including the clayey nature of the natural levee deposits at Site 10 (Geotechnical Consultants 2009a, 2009b). In addition, and as shown on Figure 5.15-1 (Project Geology Map), the Colma formation also underlies the sanitary sewer pipeline route at Site 11 and Site 17

(Alternate). Due to the dense and clayey nature of the Colma formation, these sites would also not be susceptible to liquefaction.

Moreover, the proposed facilities would be designed to meet current seismic standards in accordance with the 2010 California Building Code and with the SFPUC's General Seismic Design Requirements (see Chapter 3, Project Description, Section 3.4.2.2 [Well Facility Types]), which include characterizing and addressing the potential for liquefaction through geotechnical evaluations, building design, and pipeline construction techniques and materials, such as chained joints. Therefore, geologic impacts on people or structures related to liquefaction would be *less than significant* for these sites.

Impact Conclusion: Less than Significant

Lateral Spreading

<u>All Sites</u>

At Site 1, an isolated layer of potentially liquefiable silty sand within the upper portion of the Colma formation was identified at a depth of about 35 feet. An approximately 8-foot high embankment descending on an about 3:1 slope is located approximately 20 feet to the west of the nearest edge of the proposed well facility building at Site 1. The potential susceptibility of Site 1 to lateral spreading toward the embankment free face is considered low because the isolated layer of potentially liquefiable medium is at a depth well below the toe of the 8-foot tall embankment (Geotechnical Consultants 2012).

The potential susceptibility of the other sites to lateral spreading is considered to be low, because the Colma formation soils at the sites are not susceptible to liquefaction. Therefore, potential geologic impacts on people or structures related to lateral spreading would be *less than significant* for all the sites.

Impact Conclusion: Less than Significant

Settlement

The evaluation of impacts that follows discusses sites with less-than-significant impacts, followed by sites with significant impacts.

<u>Sites 2, 3, 4, 6, 7, 9, 10, 11, 18 (Alternate), and the Westlake Pump Station</u>

The site-specific data from the geotechnical borings at Sites 4, 6, 7, 9, and 10 indicate that these sites would be located in soils susceptible to a low hazard from settlement due to strong groundshaking during an earthquake (Geotechnical Consultants 2009a, 2009b, 2012). The low hazard is related to the relatively dense nature of the near-surface Colma formation at the sites, and the relatively thin stratum of artificial fill and silty fine sands at the sites. Sites 2, 3, 11, 18 (Alternate), and the Westlake Pump Station are located in proximity to and in similar geologic units as Sites 4 and 10 and would, therefore, likely have a similarly low hazard from settlement. Therefore, potential geologic impacts on people or structures related to settlement would be *less than significant* for these sites.

Impact Conclusion: Less than Significant

<u>Sites 1, 5, 8, 12, 13, 14, 15, 16, 17 (Alternate), and 19 (Alternate)</u>

The site-specific data from the geotechnical borings at Sites 1, 5, 8, 12, 13, 15, and 16 indicate that these sites would be located in soils susceptible to a moderately high hazard from settlement due to strong groundshaking during an earthquake (Geotechnical Consultants 2009a, 2009b, 2012). The moderately high hazard is related to the presence of compressible soils at these sites, including up to 20 feet of unsaturated, loose to medium dense fill sand near the surface of Site 1, artificial fill at Sites 5 and 12, a relatively loose layer of poorly graded sand near the upper stratum of natural levee deposits at Site 8, a loose layer of silty fine sand that spans the upper six feet of the natural levee deposits at Site 13, medium dense silty sand within the upper 15 feet at Site 15, and medium dense silty sand in the Colma Formation above the groundwater level at Site 16. Site 17 (Alternate), Site 19 (Alternate), and Site 14 are located in proximity to Sites 8, 12, and 15, respectively, and could, therefore, have similar soils with a moderately high hazard from settlement. The potential for damage and subsequent disruption of water service from settlement at these sites represents a *significant* potential impact.

Geotechnical recommendations relative to settlement are provided in the site-specific geotechnical studies prepared for Sites 1, 5, 8, 12, 13, 15, and 16 (Geotechnical Consultants 2009a, 2009b, 2012). Sites 14, 17 (Alternate), and 19 (Alternate) are adjacent to or very close to sites where a site-specific geotechnical study has been prepared, and where the design criteria for the adjacent site appear to be applicable. Mitigation Measure M-GE-3 (Conduct Site-Specific Geotechnical Investigations and Implement Recommendations) would reduce the impact of settlement on these well facilities by requiring facilities to be designed and constructed in conformance with specific recommendations contained in design-level geotechnical studies, such as over-excavation of artificial materials, re-compaction with moisture treated engineered fill, supporting structures on structurally rigid mat foundations, post-tensioning to reinforce and increase structural rigidity, and using flexible pipe connections. Therefore, geologic impacts on people or structures related to settlement following mitigation would be *less than significant* for these sites.

> ***Mitigation Measure M-GE-3: Conduct Site-Specific Geotechnical Investigation and Implement Recommendations (All Sites)***
> (See Impact GE-3 for a description)

Impact Conclusion: Less than Significant with Mitigation

Impact GE-5: The Project would not be located on corrosive or expansive soil, creating substantial risks to life or property. (Less than Significant)

<u>All Sites</u>

Soil types identified at facility sites include Orthents and Urban Land (NRCS 1991). As indicated in Table 5.15-2 (Soil Properties in the Project Area), Orthents soils have a low shrink/swell potential, while Urban Land consists of areas where more than 85 percent of the surface is covered by asphalt, concrete, buildings, and other structures. Therefore, potential soils impacts on life or property related to expansive soils would be *less than significant*.

The geotechnical investigations for Sites 5, 6, 7, 8, 9, 10, 12, 13, 15, and 16 indicated that the soils present are mildly to highly corrosive to ferrous metals (Geotechnical Consultants 2009a, 2009b). Given that the mapped soil types at other sites are similar to the confirmed soil types found at sites for which geotechnical investigations have been undertaken, it is reasonable to assume that the remaining sites would also display mild to high corrosive characteristics in soils. Corrosive soils could, over time, deteriorate the newly installed pipelines proposed under the Project. If such deterioration were to cause a rupture in the pipelines, substantial damage to adjacent properties could result from the temporary uncontrolled flow of water (until valves can be operated to cease the flow of water). However, a combination of coating and/or pipe wrapping, and possibly passive cathodic protection would be used to protect the new pipelines from corrosion. The pipeline coating would be made of materials that would prevent the external corrosion process. In addition, a cathodic protection system would be placed along the length of the new pipeline to prevent corrosion of the pipeline (see Chapter 3, Project Description, Section 3.4.2.4 [Water Connection, Sanitary Sewer, and Storm Drain Piping]). With incorporation of these design features, as proposed, soils impacts on life or property related to corrosive soils would be *less than significant.*

Impact Conclusion: Less than Significant

5.15.3.6 Cumulative Impacts and Mitigation Measures

Impact C-GE-1: Construction and operation of the proposed Project could result in significant impacts related to soils and geology. (Less than Significant)

The geographic scope for cumulative impacts on geology and soils consists of each proposed GSR facility site (including the construction area for the well, the well facility, and the pipelines) and the immediate vicinity around each of these sites. Geologic and seismic impacts are generally site-specific, because they depend upon the local geology and soil conditions.

The Peninsula Pipelines Seismic Upgrade (PPSU) Project, Colma Site (cumulative project D-1) would occur in the vicinity of Sites 8 and 17 (Alternate). Because of the dense and clayey nature of the Colma formation underlying these sites, the sites would not be subject to geologic or soil instability. Because of the localized nature of the geologic and soils impacts, the cumulative projects listed in Table 5.1-3 (Projects Considered for Cumulative Impacts), including the PPSU Project, Colma Site, would not contribute to potential cumulative impacts associated with the GSR Project, including geologic or soil instability (Impact GE-1 during construction and Impact GE-4 during operations), topographic changes (Impact GE-2), fault rupture and ground shaking (Impact GE-3) and exposure to corrosive or expansive soil (Impact GE-5). For this reason, the potential cumulative impact related to geology and soils would be *less than significant*.

5.16 HYDROLOGY AND WATER QUALITY

This section describes the existing conditions and regulatory setting for hydrology and water quality in the Project area and assesses potential impacts on hydrology and water quality that could result from implementation of the proposed Project. For construction of the Project, the surface water effects are generally associated with construction-related stormwater runoff and discharges; therefore, the study area is restricted to the individual well facility sites and the pipeline routes. For operation of the Project, surface water effects would be related to stormwater runoff from the well facilities; effects from operation of the Project could also occur in the Westside Groundwater Basin as a whole because of Project-related groundwater pumping and in-lieu recharge of the Basin. Therefore, the study area is expanded to the Westside Groundwater Basin for the analysis of impacts on groundwater from operation of the proposed Project.

5.16.1 Setting

5.16.1.1 Climate and Precipitation

The study area is located in a valley between the Pacific Ocean and San Francisco Bay, giving it a variable, but mild, marine climate. Winters are mild and moderately wet and summers are cool and dry. Most precipitation occurs as rainfall from November through April, with annual precipitation ranging from less than 20 inches along San Francisco Bay near the San Francisco International Airport (SFO) to approximately 24 inches in the center of the valley near Colma and South San Francisco (San Bruno et al. 2012).

5.16.1.2 Regional Surface Water Hydrology

San Mateo County encompasses four hydrologic basins and a total of 34 watersheds, all of which ultimately drain west to the Pacific Ocean or east to the San Francisco Bay (San Francisco Bay or Bay). The Pacific Ocean coast is located to the west of the proposed GSR facility sites and the San Francisco Bay is located to the east.

The proposed Project is located within the hydrologic boundaries of several watersheds in San Mateo County, including the watersheds of Vista Grande Drainage Canal, Colma Creek, San Bruno Creek, Green Hills Creek, and Millbrae Creek as illustrated on Figure 5.16-1 (Surface Water Hydrology Map). These watersheds are described below.

The relation of surface water features, including Lake Merced, Pine Lake, and the Golden Gate Park Lakes, to groundwater is described in Section 5.16.1.4 (Groundwater-Surface Water Interactions) below.

Data Sources: San Mateo County 2010; Oakland Museum, Upper Peninsula Watershed Finder; SF Public Works Dept. 2004. As modified by GHD 2012.

Vista Grande Canal Watershed

The Vista Grande Watershed historically drained into Lake Merced but has since been altered to flow to the Pacific Ocean. The Westlake Pump Station and Sites 1, 2, 3, and 4 would be located within the Vista Grande Watershed, with stormwater from the sites flowing northward through underground storm drains to the Vista Grande Drainage Canal. Stormwater flows through the Vista Grande Drainage Canal for about 3,500 feet before flowing into the Vista Grande Outfall Tunnel, which discharges to the Pacific Ocean through an outfall beach structure below Fort Funston in Golden Gate National Recreation Area. (San Bruno et al. 2012)

Colma Creek Watershed, including Twelve Mile Creek

Colma Creek is a small creek draining much of South San Francisco and the surrounding area before entering into San Francisco Bay just north of SFO and the eastern terminus of Interstate 380 (I-380). Sites 5 through 13 would be located within the Colma Creek Watershed. Within the valley portion of the watershed, Colma Creek is an open, concreted lined engineered channel from San Francisco Bay to near the Colma/South San Francisco city limits. This engineered section of creek is maintained by the San Mateo County Flood Control District. Much of the area upstream of South San Francisco and some small tributaries within South San Francisco flow through underground storm drains. Some of the uppermost reaches of the creek on San Bruno Mountain are natural channels (San Bruno et al. 2012). The Colma Creek Watershed includes Twelve Mile Creek, which flows northeast in underground storm drains and enters Colma Creek upstream of Woodlawn Memorial Park in the vicinity of Sites 12 and 19 (Alternate) in South San Francisco.

San Bruno Creek Watershed

San Bruno Creek flows from the uplands along the west side of the South Westside Basin near Highway 35, discharging into the Bay at a location just south of the Colma Creek discharge. Sites 14 and 15 would be located within the watershed for San Bruno Creek, which flows eastward, primarily through underground storm drains.

Green Hills Creek Watershed, including Lomita Channel and Highline Canal

Green Hills Creek flows east through underground storm drains from the Millbrae Meadows through the City of Millbrae. The creek connects to the Lomita Channel, which is an open channel that parallels the west side of U.S. Highway 101 (U.S. 101), and then to the Highline Canal also adjacent to U.S. 101. Highline Canal is an engineered concrete-lined channel that crosses under U.S. 101 and discharges to the Bay south of SFO. Site 16 would be located in the eastern portion of the Green Hills Creek Watershed, with stormwater flowing through underground storm drains to the Highline Canal adjacent to U.S. 101.

Millbrae Creek Watershed

Millbrae Creek is in the southernmost part of the South Westside Basin, with its headwaters also located in the western uplands and with a discharge to the Bay south of SFO. No GSR facility sites are planned within the Millbrae Creek Watershed.

Surface Water Quality

In accordance with Section 303(d) of the federal Clean Water Act, state governments must present the U.S. Environmental Protection Agency (U.S. EPA) with a list of "impaired water bodies." Such water bodies are defined as those that do not meet surface water quality standards, even after point sources of pollution have installed the minimum required levels of pollution control technology. This is explained in greater detail in Section 5.16.2 (Regulatory Framework). The surface water bodies in the Project area included on the list of impaired water bodies are shown in Table 5.16-1 (Impaired Surface Water Bodies). The remaining water bodies in the Project area, including the Vista Grande Drainage Canal, Twelve Mile Creek, San Bruno Creek, Green Hills Creek, Highline Canal, and Millbrae Creek are not listed as impaired water bodies (SWRCB 2007; RWQCB 2011).

TABLE 5.16-1
Impaired Surface Water Bodies

Water Body	Pollutant/Stressor
Lake Merced	Low Dissolved Oxygen, pH
San Francisco Bay (Lower)	Chlordane, DDT, Dieldrin, Dioxin Compounds (including 2, 3, 7, 8-TCDD), Exotic Species, Furan Compounds, Mercury, PCB's (Polychlorinated biphenyls), PCB's (dioxin-like), Trash (proposed)
Colma Creek	Trash (proposed)

Flood, Seiche, and Tsunami

The Federal Emergency Management Agency (FEMA) delineates regional flooding hazards as part of the National Flood Insurance Program. The most recent Flood Insurance Study for San Mateo County became effective on October 16, 2012, and investigates the existence and severity of flood hazards in the Project area (FEMA 2012). The primary area of mapped 100-year flooding in the Project area is located along Colma Creek in the City of South San Francisco, near Site 9. A Colma Creek Flood Control Zone was created in 1964 by the San Mateo County Flood Control District to alleviate flooding in the City of South San Francisco. Flood control projects have included channel and culvert improvements, as well as bridge replacements. Localized areas of 100-year flooding are also located in South San Francisco at the intersection of Spruce Avenue and Huntington Avenue near Site 13 and in Millbrae along the Lomita Channel, which flows adjacent to U.S. 101 east of Site 16. The City of San Bruno has no mapped flood hazard areas identified (FEMA 2012).

Water supply reservoirs in San Mateo County can also present a remote risk of downstream inundation in the event of a dam failure. Dam failure inundation maps prepared by the Association of Bay Area Governments (ABAG) and San Mateo County indicate that the proposed Project is not located within an area subject to inundation from failure of a levee or dam (ABAG 2012; San Mateo County 2005).

Flooding hazards can also occur as a result of seiches (i.e., earthquake-induced oscillating waves in an enclosed water body) and tsunamis (i.e., earthquake-induced waves formed in the open ocean that reach a shoreline). The proposed Project is not located near isolated bodies of water that would be subject to inundation by seiche, and the proposed well sites are not located within an area subject to inundation from tsunami (Cal EMA 2009).

5.16.1.3 Regional Groundwater Hydrology

Most of northern San Mateo County is underlain by the Westside Groundwater Basin, shown on Figure 5.16-1 (Surface Water Hydrology Map) (DWR 2006). With an area of about 45 square miles, this groundwater basin extends from San Francisco south to San Mateo County. The Westside Groundwater Basin is separated from the Lobos Basin to the north by a northwest-trending bedrock ridge through the northeastern part of Golden Gate Park. San Bruno Mountain and San Francisco Bay form the eastern boundary, and the San Andreas Fault and Pacific Ocean form the western boundary. The southern limit of the Westside Groundwater Basin, which roughly follows the Burlingame-San Mateo common city limit, is defined by an area of high bedrock that separates it from the San Mateo Plain Groundwater Basin. The basin opens to the Pacific Ocean on the northwest and San Francisco Bay on the southeast.

There is no geologic feature that restricts groundwater flow between the northern and southern parts of the groundwater basin. However, groundwater development in the two parts of the Basin are different from each other, as groundwater has been more heavily developed as a water supply in the South Westside Groundwater Basin. For discussion purposes, the 14-square-mile portion of the Westside Groundwater Basin north of the San Francisco/San Mateo County line is referred to in this EIR as the North Westside Groundwater Basin and the 31-square-mile portion of the Westside Groundwater Basin south of the San Francisco/San Mateo County line is referred to herein as the South Westside Groundwater Basin. The South Westside Groundwater Basin underlies Daly City, Colma, South San Francisco, San Bruno, Millbrae, and portions of unincorporated San Mateo County, Burlingame, and Hillsborough.

Regional Geology

The five major geologic units in the Westside Groundwater Basin are the Mesozoic-age Franciscan Complex, Pleistocene-age Merced and Colma Formations, and the Pleistocene to recent Dune Sands and Bay Mud deposits. There are also minor, but widespread, units of recent alluvium along historical stream channels. (LSCE 2010)

Exposed in the low hills east and northeast of Lake Merced, the Franciscan Complex forms the basement rock for the aquifer system, which defines the lateral and vertical limits of the primary groundwater-bearing formations in the Westside Groundwater Basin. To the north of Lake Merced, the bedrock slopes gently westward towards the Pacific Ocean; beneath Golden Gate Park there is an apparent buried stream valley that results in a thicker accumulation of sediment in that area. South of Lake Merced to the Daly City area, the surface of the bedrock slopes southwestward to Daly City, occurring at depths of almost 600 feet near the center of Lake Merced and nearly 1,000 feet beneath the southern portion of Daly City. The bedrock configuration is more speculative beneath the Pacific Ocean, to the west of the Westside Groundwater Basin.

The Merced Formation is a 5,000-foot-thick sequence of shallow marine and non-marine deposits comprising three units (lower, middle, and upper). It is the thickest water-bearing formation overlying the basement rock (see Figure 5.16-2 [North South Geologic Cross Section, Westside Groundwater Basin]). The lower unit of the Merced Formation is about 4,000 feet thick and is composed of fine sandstone to siltstone. This unit is strongly to moderately deformed and shows some evidence of folding. The middle unit of the Merced Formation is up to about 600 feet thick and is composed of thinner bedded, near-shore marine, beach, estuary, dune, and fluvial deposits of fine sandstone, siltstone, and mudstone. The middle unit of the Merced Formation is moderately deformed with some evidence of folding and steeper dip near the Serra Fault. The upper unit of the Merced Formation is approximately 500 feet thick and consists of a sequence of thin bedded beach, dune, estuarine, and fluvial deposits of weakly consolidated fine sandstone with some gravel and mudstone beds. This unit is only deformed in a minor fashion. A thick clay unit referred to as the "W" clay layer is present in this unit.

The Colma Formation and Dune Sands comprise the majority of the surficial geologic units in the North Westside Groundwater Basin. The Colma Formation is a surficial unit consisting of fine- to medium-grained sand with some clay, silt, and gravel beds of fluvial, floodplain, alluvial fan, and dune sand origin. It is exposed from Lake Merced, south to San Bruno, and the maximum thickness is about 200 feet. The separation between the Colma Formation and the underlying Merced Formation is not clearly defined because of the similarity in the geologic materials comprising the units.

Dune Sands are also a surficial unit of fine- to medium-grained sands that are exposed across the San Francisco Peninsula north of Lake Merced. Because of the similarity in geologic materials comprising the Dune Sands and older formations, there is uncertainty regarding the thickness of this unit.

The Bay Mud deposits generally consist of clays and silts with some sand. In the Westside Groundwater Basin, the extent of this surficial unit is limited to the San Francisco Bay shore in the South Westside Groundwater Basin.

There are two primary structural features affecting the groundwater basin, including the San Andreas Fault system and the Serra Fault. The northwest-trending San Andreas Fault system, defining the southwest boundary of the Westside Groundwater Basin, is an active right-lateral, strike-slip fault with the west side moving northward relative to the east side. The Serra Fault parallels the San Andreas Fault and is a southwest dipping reverse fault with the west side up thrust relative to the east side. The fault extends from south of San Bruno to the Lake Merced area and extends offshore.

North-South Geologic Cross Section, Westside Groundwater Basin

Regional Groundwater Storage and Recovery Project

Figure 5.16-2

This page left intentionally blank

Offshore of the Westside Groundwater Basin, the ocean floor dips gently westward with ocean depths reaching only 60 feet at two miles offshore, 100 feet at eight miles offshore and 300 feet at 25 miles offshore at the edge of the continental shelf. The continental shelf is underlain by a thick sequence of Quaternary and Tertiary age sedimentary deposits, crossed by the San Andreas Fault approximately two miles offshore, and possibly crossed by the Serra Fault as well. These faults may act as hydraulic barriers and, combined with the thick sequence of sedimentary rocks beneath the ocean floor, may preclude direct communication between the water-bearing units of the Westside Groundwater Basin and the Pacific Ocean.

South Westside Groundwater Basin Geology

The majority of the surficial geologic units in the South Westside Groundwater Basin are composed of the Colma and Merced Formations. In the Daly City and Colma area, the upper Merced is poorly defined, massive, fine-grained sand to sandstone with thinner, discontinuous clay horizons. The upper 200 feet of these deposits (Colma Formation) appear to be more non-marine in nature, possibly reflecting alluvial fan aprons or dune fields fed by sources from the north and, possibly, the south. (LSCE 2010)

Beneath the Colma area, a thick sequence of massive fine sand occurs with a few thin clay beds. Overlying the thick sands in the Colma area is a surficial clayey sand to clay and sand that is interpreted to be a weathered zone of the Colma Formation and younger units. The higher, finer-grained clay and sand sequence appears to thicken and grade into clay beds toward the Bay. These relationships may reflect changing depositional character, from sand-dominated upper Merced and Colma to the west, to the fine-grained estuary and mudflat deposits of the San Francisco Bay region to the east. (LSCE 2010)

In the San Bruno area, well logs and geophysical logs indicate a deep sandy unit overlain by about 200 to 250 feet of predominately fine-grained material that includes silts, clays, sandy clays, and gravelly clays. A southward extending ridge of Franciscan bedrock along with fine-grained Bay Deposits appear to separate San Bruno from the San Francisco Bay to the east. South of San Bruno, surficial mapping may indicate a relationship to exposures of sand and gravel deposits in the Burlingame area, which are mapped as non-marine Santa Clara Formation. (LSCE 2010)

Aquifer System

The Westside Groundwater Basin includes three aquifers informally known as the Shallow Aquifer, Primary Production Aquifer, and Deep Aquifer shown on Figure 5.16-2 (North South Geologic Cross Section, Westside Groundwater Basin) (LSCE 2010). In the North Westside Groundwater Basin, the Shallow Aquifer is present to a depth of about 100 feet and the aquifer is unconfined. In the Lake Merced area and southern portion of the Sunset District, south to Daly City, this aquifer is separated from the Primary Production Aquifer by the "-100-foot clay" layer. The Primary Production Aquifer is at least partially confined and is separated from the Deep Aquifer by the "W" clay layer, and also includes two discontinuous clay layers referred to as the "X" and "Y" clay layers that may locally restrict groundwater flow within the aquifer. The Deep Aquifer underlies the "W" clay layer.

The -100-foot clay layer and "W" clay layer extend north approximately to the vicinity of where the West Sunset well facility is proposed; these clay layers are absent from that point to the northern extent of the groundwater basin. Because these clay layers are absent, the aquifers are hydraulically connected and can effectively be considered one aquifer beneath Golden Gate Park. The Shallow Aquifer is absent in the South Westside Groundwater Basin from Daly City to the south.

Cross-section data oriented north-south and east-west through the South Westside Basin indicate that from Daly City south to South San Francisco, the Primary Production Aquifer is separated from shallow groundwater by at least 50 feet to 100 feet aggregate thickness of intervening clay and sand deposits. Some groundwater elevation data suggest the shallowest groundwater may be locally perched. The relatively low-permeability shallow sediments in the Daly City to South San Francisco area are markedly different than the higher-permeability shallow sands found in the North Westside Basin. South of Daly City in the eastern area of South San Francisco, San Bruno, and Millbrae, the presence of thick surficial Bay Mud deposits of even lower relative permeability likely provides an even greater degree of isolation to the Primary Production Aquifer in that area. (Kennedy/Jenks May 2012e)

Additional evidence for hydraulic separation between shallow groundwater and the Primary Production Aquifer beneath Colma and Millbrae is apparent from relative groundwater levels measured in multi-level Project monitoring well clusters installed in 2008 and 2009. At each monitoring well location, there are three or four separate wells installed at discrete depths. The completion depths for these wells generally correspond to potential water bearing zones in the Primary Production Aquifer and the Deep Aquifer. Differences in groundwater levels measured in the Project monitoring wells suggest the presence of unsaturated zones and localized perched water at shallow depths and likely hydraulic separations between the localized perched zones, shallow groundwater zones, Primary Production Aquifer, and Deep Aquifer in the central and southern portions of the South Westside Basin. (Kennedy/Jenks 2012e)

Groundwater Monitoring Network and Program

The SFPUC, in cooperation with its Partner Agencies,[1] has implemented a groundwater monitoring program since 2001 to evaluate groundwater and lake elevations and groundwater quality throughout the Westside Groundwater Basin, including both the North and South Basins and the portion of the Basin near Lake Merced. (Kennedy/Jenks 2012d)

A network of monitoring facilities consisting of 46 wells includes existing monitoring wells plus new monitoring wells that have been installed at Sites 1, 2, 5, 7, 8, 9, 10, 11, 12, 13, 15, and 16 (see Chapter 3, Project Description, Section 3.4.3 [Facility Sites]). Several of the monitoring wells are "nested;" that is, multiple wells are located together in the same borehole and screened at different depths. In addition, two monitoring well clusters are used to collect groundwater level and groundwater quality data near the San Francisco Bay (see Figures 5.16-3 [Groundwater Quality Monitoring Network] and Figure 5.16-4

[1] Since the 1990s the SFPUC has worked cooperatively on Westside Groundwater Basin investigations, monitoring and coordinated studies with the Partner Agencies (SFPUC 2011b).

[Groundwater Elevation Monitoring Network]). Those wells that comprise the monitoring network in the North Westside Groundwater Basin are also shown on Figures 5.16-3 and 5.16-4.

The coastal monitoring network consists of five locations in San Francisco along the Pacific Coast extending from the western end of Golden Gate Park south to the vicinity of Lake Merced (South Windmill Replacement, Kirkham, Ortega, Taraval, and Zoo). Each monitoring location includes two to four individual monitoring wells completed at different depths to monitor groundwater levels and quality in the Shallow, Primary Production and Deep aquifers. Each well in the coastal monitoring network is sampled for water quality parameters that are indicative of the potential for seawater intrusion, including chloride, total dissolved solids (TDS), and electrical conductivity.

The lake-aquifer monitoring network around Lake Merced includes continuous monitoring of water levels in South Lake and a dedicated network of eight monitoring sites that include four groundwater monitoring well clusters (LMMW1, LMMW2, LMMW3, and LMPS MW) around Lake Merced that are screened in the Shallow, Primary Production, and Deep aquifers to provide data on lake-aquifer interactions. Each of these well clusters includes at least one well screened in the Shallow Aquifer. At some locations there are two wells completed in the Shallow Aquifer, with one well completed in the shallower part of the aquifer (designated with an “SS”) and one well completed in the deeper portion of the Shallow Aquifer (designated with an “S”). The remaining monitoring sites include monitoring wells screened in the Shallow Aquifer (LMMW4, LMMW7, LMMW8, and LMMW9). An additional well cluster (LMMW-5SS and 5S) is located near Pine Lake. Water levels in Lake Merced are monitored on a continuous basis, and additional monitoring is conducted on a periodic basis.

Three monitoring well clusters in the South Westside Groundwater Basin are used to collect groundwater level and groundwater quality data near the San Francisco Bay (Figures 5.16-3 and 5.16-4, Groundwater Quality Monitoring Network and Groundwater Elevation Monitoring Network, respectively). The “SFO” well cluster consists of two wells that were installed in the northern portion of SFO in 2006. These wells are identified as SFO-S and SFO-D: SFO-S is 74 feet deep and monitors the shallow groundwater zones; and SFO-D is 146 feet deep and monitors the Primary Production Aquifer. The “UAL” well cluster also consists of two wells that were installed in the southern part of SFO in 2003. These wells are identified as UAL MW13C and UAL MW13D: UAL MW13C is 146 feet deep and monitors the Primary Production Aquifer; and UAL MW13D is 41.5 feet deep and monitors the shallow groundwater zones. The southernmost monitoring well cluster was installed in 2006. The three wells in this cluster are identified as Burlingame-S, Burlingame-M, and Burlingame-D: Burlingame-S is 98 feet deep and monitors the shallow groundwater; Burlingame-M is 166 feet deep; and Burlingame-D is 280 feet deep and monitors the Primary Production Aquifer. Groundwater Levels and Flow Directions

North Westside Groundwater Basin

Prior to the early 1940s, water levels in the North Westside Groundwater Basin and in the northern portions of San Mateo County were above sea level, with a northwesterly gradient in the shallow and primary production aquifers (SFPUC 2005). Based on regular monitoring of groundwater levels in the North Westside Groundwater Basin since 2004, groundwater levels along the Pacific Ocean coast, north of Lake Merced, generally remain above sea level in the Shallow and Primary Production Aquifers, with the exception of Primary Production Aquifer groundwater levels in the vicinity of South Windmill location in Golden Gate Park where irrigation season groundwater levels have been below sea level (SFPUC 2011b). At the San Francisco Zoo, groundwater levels have, during drought periods, occasionally declined to levels slightly below sea level. At the South Windmill location, Primary Production Aquifer levels periodically decrease below sea level due to irrigation pumping at the South Windmill Replacement well.

In the southern portion of Lake Merced, Primary Production Aquifer groundwater levels in LMMW-3D have historically been below sea level, probably due to pumping in the adjacent South Westside Groundwater Basin. Primary Production and Deep Aquifer levels in the North Westside Groundwater Basin have historically decreased to below sea level at some locations, but since 2001 (Primary Production Aquifer) and 2004 (Deep Aquifer), when comprehensive monitoring began, were generally on the rise.

Groundwater levels generally remained stable or increased from 2004 through 2010 (SFPUC 2012e). The increase is likely due to decreased pumping from the groundwater basin including reduced golf club irrigation pumping in the vicinity of Lake Merced and reduced municipal pumping in the South Westside Groundwater Basin under the In-Lieu Recharge Demonstration Study (discussed below) (LSCE 2005). In 2010, the groundwater flow direction in the Shallow Aquifer of the North Westside Groundwater Basin was westerly and groundwater levels ranged from approximately 10 to 39 feet, pursuant to the North American Vertical Datum of 1988 (NAVD 88)[2]. North of Lake Merced, the groundwater flow direction in the Primary Production Aquifer was also westerly and groundwater levels ranged from approximately 3 to 77 feet NAVD 88. South of Lake Merced, the groundwater flow in the Primary Production Aquifer shifts to the south toward the South Westside Groundwater Basin, with groundwater levels dipping to approximately -15 feet NAVD 88 at LMMW-6D, the

---

[2] Groundwater elevations are commonly referenced to the North American Vertical Datum of 1988 (NAVD 88) and/or the National Geodetic Vertical Datum of 1929 (NGVD 29). NAVD 88 was established in 1991 and is the most up-to-date and accurate datum. NGVD 29 was used by surveyors and engineers for most of the 20th century and is 2.8 feet lower than NAVD 88 in San Francisco and northern San Mateo County. The technical reports prepared in support of the GSR Project used both datums; therefore, for consistency, this EIR uses the same datum employed in a given technical report when discussing information obtained from that report. Mean sea level is equivalent to 0 feet NGVD 29, which is also equivalent to 2.8 feet NAVD 88.

southernmost groundwater monitoring well in the Primary Production Aquifer in the North Westside Groundwater Basin.

South Westside Groundwater Basin

Beginning in the 1950s and 1960s, groundwater levels in the South Westside Groundwater Basin declined to below sea level. This decline continued into the 1970s, after which groundwater levels stabilized at elevations of more than 100 feet below mean sea level (msl), resulting in vacated aquifer storage[3] of up to 75,000 acre-feet (af) in the Daly City, South San Francisco, and northern San Bruno areas (Kirker, Chapman & Associates 1972; LSCE 2005).

In 2005, groundwater elevations in the Primary Production Aquifer in the South Westside Groundwater Basin ranged from approximately -8 feet NAVD 88 immediately south of Lake Merced to -102 feet NAVD 88 in Daly City and -75 feet NAVD 88 in South San Francisco. At that time, groundwater flow in the vicinity of Lake Merced continued to be to the south; the steepest groundwater gradient was between Lake Merced and Daly City (LSCE 2006). On the bayside, groundwater levels in the Primary Production Aquifer beneath San Bruno were approximately -180 feet NAVD 88 in 2005.

The depth to groundwater in the South Westside Groundwater Basin is largest in the eastern area of Daly City and in San Bruno in the Primary Production Aquifer. Overall, the depth to groundwater in the Primary Production Aquifer ranges from 200 feet to 300 feet below ground surface in the Daly City area, within 50 feet to 100 feet of the ground surface in the California Water Service Company (Cal Water) service area, and about 260 to 270 feet below ground surface in the San Bruno area (SFPUC 2011b). At the southern portion of Lake Merced and immediately to the south, the groundwater flow direction in the Primary Production Aquifer is to the south and southeast towards Daly City. In these areas and further south, the depth can exceed 300 feet below ground surface, due largely to the effects of long-term pumping in the Daly City, Colma, South San Francisco, and San Bruno areas. The groundwater depressions caused by concentrated areas of long-term pumping induce flow locally towards those depressions.

In the South Westside Groundwater Basin, shallow groundwater is also present within shallow units overlying the Primary Production Aquifer. In the eastern portion of the Basin from South San Francisco southward to Burlingame, shallow groundwater generally flows east towards the Bay. Throughout this eastern portion of the Westside Basin, groundwater flow in the Deep Aquifer is also generally east toward the Bay. In the vicinity of San Bruno, groundwater extraction has created a depression in the groundwater levels. A flow divide near the south end of SFO separates the area where groundwater flows toward the pumping depression in San Bruno from the area where groundwater flows toward the Bay. The divide trends southwest from near the Millbrae exit on U.S.

[3] Vacated aquifer storage is the volume of groundwater which is estimated to have been present historically in the aquifer, but which is no longer present, usually due to pumping.

101; groundwater northwest of the divide is captured by the City of San Bruno wells. (Kennedy/Jenks 2012e)

In-Lieu Recharge Demonstration Study

The SFPUC and the Partner Agencies participated in the In-lieu Recharge Demonstration Study in the South Westside Groundwater Basin from October 2002 through April 2007 to study the effects of the groundwater recharge component of a conjunctive use program, in which the Partner Agencies received supplemental surface water from the SFPUC in-lieu of their normal groundwater pumping. The purpose of the Demonstration Study was to determine if this in-lieu recharge would result in an accrual of groundwater storage that would result in an increase in groundwater availability for pumping in dry years and for emergency supply when the regional water system supply may be reduced. (Kennedy/Jenks 2012a)

The SFPUC undertook groundwater monitoring throughout the South Westside Groundwater Basin and adjacent areas along the Pacific Coast and San Francisco Bay, before, during, and after the Demonstration Study to determine the extent to which groundwater levels and storage were affected. After approximately three years (from fall 2002 to spring 2005) of operating the Demonstration Study, the SFPUC reported that in-lieu recharge can be successfully accomplished by reducing pumping, resulting in increases in groundwater storage. As expected, monitoring results indicated that reduction of pumping by the Partner Agencies resulted in increased groundwater levels in the Primary Production Aquifer, where the Partner Agencies' wells are screened. (LSCE 2005)

During the In-lieu Recharge Demonstration Study, the SFPUC delivered approximately 20,000 af of supplemental surface water to the Partner Agencies in exchange for a reduction in their groundwater pumping. This 20,000 af has been credited to the SFPUC Storage Account. However, this water would not be withdrawn unless and until the GSR Project and the Operating Agreement are approved by the SFPUC and the Project wells are constructed to enable use of the water in storage (see explanation of the SFPUC Storage Account in Chapter 3, Project Description, Section 3.8.1 [Operating Agreement]). (Kennedy/Jenks 2012a)

Seawater Intrusion

Seawater intrusion refers to the migration of seawater into a freshwater aquifer and can occur when groundwater levels are lowered by pumping. Seawater intrusion becomes an environmental concern when the degradation of groundwater quality would make the groundwater potentially unsuitable for its identified use, or when inland surface water features are affected by the seawater, compromising habitats or uses of the surface water.

Two areas of the Westside Groundwater Basin are susceptible to seawater intrusion under certain conditions. One area is in the North Westside Groundwater Basin along the Pacific Coast, where the Shallow Aquifer is open to the ocean; this area is discussed below in Section 5.16.1.3 (Regional Groundwater Hydrology) under the sub-heading "Seawater Intrusion in the North Westside Groundwater Basin." The other is in the South Westside Groundwater Basin along San Francisco Bay.

Seawater Intrusion in the North Westside Groundwater Basin

In the North Westside Groundwater Basin, the Shallow Aquifer is in direct hydraulic connection with the Pacific Ocean between Lincoln Park (north of Golden Gate Park) and the San Francisco Zoo area, indicating a potential for seawater intrusion to occur in the Shallow Aquifer in this area. Although existing offshore seismic studies suggest that there might be some depositional or structural features in the offshore sediments that would preclude seawater intrusion directly from the ocean into the Primary Production and Deep Aquifers, the geologic information for this offshore area is not sufficient to conclusively make this determination (Kennedy/Jenks 2012c). Therefore, seawater intrusion into the Primary Production Aquifer as a result of direct hydraulic connection with the ocean is considered possible.

If seawater intrusion were to occur within the Shallow Aquifer, the Primary Production Aquifer could also be affected in areas where no clay layer separates the aquifers or where gaps are present in the clay layers that separate the aquifers, assuming a downward hydraulic gradient between the two aquifers. South of the Sunset area in western San Francisco, the -100-foot clay layer separating the Shallow Aquifer and the Primary Production Aquifer may protect the Primary Production Aquifer from seawater intrusion occurring in the Shallow Aquifer (if it were to occur). However, there are gaps in the -100-foot clay layer (as illustrated in Figure 5.16-2 [North-South Geologic Cross Section, Westside Groundwater Basin]), including one between the Taraval and San Francisco Zoo coastal groundwater monitoring locations (refer to Section 5.16.1.3 [Regional Groundwater Hydrology] under the sub-heading “Groundwater Monitoring Network and Program”). At these gaps the Shallow and Primary Production Aquifers could be hydraulically connected. North of the Sunset District, including Golden Gate Park, there are not pronounced or laterally extensive clay layers and the Shallow Aquifer and Primary Production Aquifers are merged, meaning that in this area the aquifers are hydraulically connected to a greater degree and can effectively be considered one aquifer. South of the San Francisco Zoo, in the vicinity of Lake Merced, the Serra Fault could act as a barrier to seawater intrusion as far north as the Great Highway, where the fault heads offshore. (LSCE 2010)

<u>Coastal Groundwater Levels</u>

Coastal groundwater levels measured in the coastal monitoring network, as described in Section 5.16.1.3 (Regional Groundwater Hydrology) under the sub-heading “Groundwater Monitoring Network and Program”, provide an indication of the potential for seawater intrusion to occur. In general, the potential for seawater intrusion is lower when coastal groundwater levels are above sea level. Although coastal groundwater levels that are below sea level indicate a higher potential for seawater intrusion, the occurrence of seawater intrusion would need to be confirmed through other means, such as groundwater quality monitoring.

Shallow Aquifer Coastal Groundwater Levels

Through 2010, groundwater levels in all Shallow Aquifer coastal monitoring wells have been consistently above sea level, except at the South Windmill Deepwell monitoring location (USGS

South Windmill MW-57). Groundwater levels in the Shallow Aquifer at the South Windmill monitoring location have varied as much as approximately 19 feet seasonally and have historically declined to below sea level by as much as 2 feet during the irrigation season. However, none of the groundwater levels were below sea level in 2010, likely because of reduced irrigation pumping at the South Windmill Deepwell facility (SFPUC 2011b).

Primary Production Aquifer Coastal Groundwater Levels

Primary Production Aquifer groundwater levels at the coastal monitoring locations have consistently remained above sea level, except for brief deviations below sea level at the San Francisco Zoo location. At the Kirkham location, the Primary Production Aquifer groundwater levels also show a seasonal variation that may be a response to pumping at the South Windmill Deepwell facility, with dry-season elevations as low as approximately 3 feet NAVD 88 in 2007. (SFPUC 2011b)

Continuous monitoring at the South Windmill Deepwell location (USGS South Windmill MW-140[4]) was not conducted in the Primary Production Aquifer until 2008; however, current monitoring indicates that Primary Production Aquifer groundwater levels at this location have declined to below sea level by as much as 20 feet during the irrigation season while rebounding to above sea level by as much as 13 feet during the wet season. Groundwater levels in the Primary Production Aquifer at the South Windmill location have not shown the same declining trend as groundwater levels in the shallower portion of the aquifer at this monitoring location. (SFPUC 2011b)

Deep Aquifer Coastal Groundwater Levels

Groundwater levels in the Deep Aquifer have periodically declined to below sea level at the Kirkham, Ortega, Taraval, and San Francisco Zoo monitoring locations (SFPUC 2011b). In August and September 2007, groundwater levels in the Deep Aquifer at the Kirkham location were briefly as much as -1 foot NAVD 88. At the Ortega monitoring location, groundwater levels in the Deep Aquifer were below sea level for parts of 2006 and 2007, with the deepest elevation of -5 feet NAVD 88; groundwater levels at this location have been on the rise and consistently above sea level since 2008. At the Taraval monitoring location, groundwater levels were below sea level for most of the period between August 2004 and January 2009, declining to a minimum of -9 feet NAVD 88 in September 2007. Since late 2009, Deep Aquifer groundwater levels at this location have been above sea level, reaching approximately 4 feet NAVD 88 by the end of 2010. Except for March and April 2006, Deep Aquifer groundwater levels at the San Francisco Zoo monitoring location were consistently below sea level between January 2004 and January 2009 due to

[4] Note that this well is screened at an elevation that corresponds to the upper part of the Primary Production Aquifer as it exists further to the south where it is separated from the Shallow Aquifer by a clay layer. However, the sand pack extends partially into the uppermost portion of the aquifer. (SFPUC 2011a)

pumping at San Francisco Zoo Well No. 5 and Daly City's municipal wells, with a minimum elevation of approximately -14 feet NAVD 88. Throughout 2010, Deep Aquifer groundwater levels at this location have been much higher, ranging from about -2 to 2 feet NAVD 88. (SFPUC 2011b)

Coastal Chloride Concentrations

With the exception of the South Windmill Deepwell monitoring location in the southwestern part of Golden Gate Park (discussed below), chloride concentrations in the coastal monitoring wells were less than 75 milligrams per liter (mg/L) between 2004 and 2011. The highest concentrations were detected at the San Francisco Zoo monitoring location, and observed concentrations over the six years of reported monitoring data for all four locations are relatively constant (SFPUC 2011b). These results indicate that seawater intrusion into the Shallow, Primary Production, and Deep Aquifers has not occurred despite long-term irrigation pumping at the zoo since the 1930s and in Golden Gate Park since the 1920s.

Between 2006 and 2010, chloride concentrations in the uppermost portion of the aquifer at the South Windmill monitoring location ranged from a low of 115 mg/L in April 2006 to a high of 193 mg/L in November 2009. Since 2009, chloride concentrations have decreased; the concentration in November 2011 was 154 mg/L. Chloride concentrations in the Primary Production Aquifer at the South Windmill monitoring location ranged from a low of 48 mg/L in October 2007 to a high of 70 mg/L in November 2009. Since 2009, chloride concentrations have decreased; the concentration in November 2011 was 59 mg/L.

Monitoring results indicate that the highest chloride concentration (393 mg/L) was detected in the November 2009 Shallow Aquifer groundwater sample from well LMMW-1S; this well is not part of the coastal monitoring network but is located between Lake Merced and the Pacific Ocean (SFPUC 2011b). As of November 2011, this concentration had declined to 260 mg/L. The maximum chloride concentration in the Primary Production Aquifer at the same location (LMMW-1D) was 105 mg/L. The cause of these high chloride concentrations is unknown. While the proximity of these wells to the Pacific Ocean (which is approximately 1,300 feet to the west) indicates that the ocean is a potential source, LMMW-1S is separated from the ocean by the Serra Fault, which acts as a barrier to seawater intrusion (Kennedy/Jenks 2012c). Further, groundwater level elevations in this well have historically exceeded 12 feet, NAVD 88, and the average pH of the groundwater at this location is 6.8, which suggests a freshwater source and is lower than the pH of seawater (about 7.8 to 8.4). In addition, this pH is lower than the values measured in other monitoring wells in the basin (7.2 to 8.6), and other chemical constituents are not typical of seawater (Kennedy/Jenks 2012c).

Seawater Intrusion in the South Westside Groundwater Basin

Because the South Westside Groundwater Basin is in contact with the San Francisco Bay, seawater intrusion is possible along the eastern edge of the basin. The Bay Mud observed along the eastern edge of the Basin may impede seawater intrusion. However, the Bay Mud may also contain connate[5] waters with high salinity. Because the Bay Mud was deposited in the San Francisco Bay, any connate water in the Bay Mud will have salinities similar to seawater, and it will be difficult to distinguish between the two. Flow of these connate waters into the South Westside Groundwater Basin would have an impact identical to seawater intrusion.

The northwestern-most edge of the South Westside Groundwater Basin is in contact with the Pacific Ocean. The section that is in contact with the Pacific Ocean is west of the Serra Fault. The Serra Fault, along with steeply dipping and offset beds of the Merced Formation, likely provides a barrier to seawater intrusion (LSCE 2010; Kennedy/Jenks 2012c). Therefore, the main portion of the South Westside Groundwater Basin is not susceptible to seawater intrusion from the Pacific Ocean.

Groundwater Levels Relative to Sea Level

Shallow groundwater zone

Groundwater levels for the shallow groundwater zone near the San Francisco Bay are obtained from the SFO-S, Burlingame-S, and UAL MW13D monitoring wells. Groundwater levels measured in these wells have been consistently at or above zero feet NAVD 88. Groundwater levels in the SFO-S monitoring well have been measured since November 2006 and are consistently found at approximately 2 feet NAVD 88. Groundwater levels in UAL MW13D have been measured since 2000 and are consistently between zero and 3 feet NAVD 88. Groundwater levels in Burlingame-S have been measured since November 2006 and seasonally fluctuate between approximately 1.5 and 4 feet NAVD 88. The groundwater levels in the Burlingame-S monitoring well show a slight declining trend.

Primary Production Aquifer

Groundwater levels for the Primary Production Aquifer near the bayside are obtained from the SFO-D and UAL MW13C monitoring wells. Groundwater levels measured in these wells have been consistently between -29 and -35 feet NAVD 88. Groundwater levels in well SFO-D have been measured since November 2006, and show minor fluctuation between -29 and -31 feet NAVD 88. Groundwater levels in well UAL MW13C have been measured since 2000, and fluctuate between approximately -32 and -35 feet NAVD 88.

Chloride Concentrations as an Indicator of Seawater Intrusion

Chloride concentrations are generally higher in the northern portion of the bayside and lower in the southern portion of the bayside.

[5] Connate waters are seawater trapped in a formation when the sediments are deposited.

The two monitoring wells in the northernmost SFO well cluster both show chloride concentrations above the secondary MCL[6] of 250 mg/L (SFPUC 2012e). Chloride concentrations in the shallow monitoring well SFO-S have ranged between 8,400 and 12,000 mg/L with an average concentration of 9,910 mg/L, and do not show an increasing trend. Chloride concentrations in the deeper monitoring well SFO-D are generally at or below 500 mg/L with the exception of a single measurement of 2,210 mg/L, and show no apparent trend. These concentrations suggest either connate water or seawater has intruded into the shallow groundwater at this site. The chloride concentrations in the Primary Production Aquifer at this site are above the secondary MCL.

The two monitoring wells in the UAL cluster both show chloride concentrations above the secondary MCL of 250 mg/L. In 2006, a sample from the shallow monitoring well MW13D showed a chloride concentration of 13,000 mg/L. In 2006 and 2007, samples collected from monitoring well MW13C in the Primary Production Aquifer showed chloride concentrations of 510 and 530 mg/L (WRIME 2007).

The three monitoring wells in the southernmost Burlingame cluster show relatively lower chloride concentrations compared to the other two well clusters. Chloride concentrations in the shallow well Burlingame-S have ranged between 110 and 518 mg/L and show an increasing trend. Chloride concentrations in the middle Burlingame-M monitoring well have ranged between 63 and 140 mg/L. Chloride concentrations in the deep well Burlingame-D have ranged between 41 and 140 mg/L. These concentrations suggest either seawater or saline connate waters may have intruded into the shallow aquifer at this site (SFPUC 2010a). Detected chloride concentrations from the remaining San Bruno wells are below the secondary MCL (SFPUC 2011b).

Groundwater Budget

A groundwater budget (also referred to as a water balance or hydrologic budget) is a measure of the balance between the quantity of water supplied to a groundwater basin and the amount leaving the basin (Todd 1980). Groundwater entering a groundwater basin is called an "inflow," and groundwater leaving the basin is called an "outflow." The volume of groundwater in a basin is called "groundwater storage," and storage changes as the respective quantities of groundwater inflow and outflow vary from season to season and from year to year.

In the Westside Groundwater Basin, inflow or recharge components of the groundwater basin include subsurface inflows from outside of the basin, recharge from precipitation, recharge from applied water (irrigation), recharge from surface water such as Lake Merced and Pine Lake, and recharge from leakage of sewer and water pipes (LSCE 2010). Outflow components include groundwater pumping, subsurface outflows to the Pacific Ocean, and discharge to Lake Merced. Lake Merced can either lose water to the

---

[6] The U.S. EPA and Title 22 of the California Code of Regulations establish secondary Maximum Contaminant Limits (MCLs) to prevent drinking water that may appear colored or taste or smell bad, causing people to stop using water from their public water system These contaminants are not considered to present a risk to human health at the Secondary MCL, but are enforceable by the State nonetheless.

groundwater system or gain water and, therefore, can be considered a component of groundwater inflow or outflow, depending on lake and groundwater levels, which vary seasonally and annually. Pine Lake, on the other hand, discharges water to the groundwater system and would only be considered a component of the groundwater inflow.

The predicted average annual groundwater budget for the Westside Groundwater Basin under modeled existing conditions is shown in Table 5.16-2 (Modeled Annual Average Groundwater Budget for the Westside Groundwater Basin under Modeled Existing Conditions). As with all of the other modeling scenarios, the modeled existing conditions scenario includes a design drought for planning purposes (see Section 5.1 Overview, Section 5.1.6.1 [Westside Basin Groundwater Model]). This drought is longer than any experienced in the available historical record (1958-2005) and is largely responsible for the predicted overall negative change in annual average storage shown in Table 5.16-2.

The predicted annual decline in groundwater storage under modeled existing conditions is primarily due to the assumptions used for the hydrologic inputs to the modeling which are consistent with the design drought used in the PEIR (San Francisco Planning Department 2008). The design drought extends the 1976-77 drought. As a result, the modeling assumes a rainfall deficit over the 47-year modeling period of nearly 20 inches compared to the 1958-2005 sequence used in the HydroFocus 2008 No-Project Scenario (HydroFocus 2011). Over the duration of the HydroFocus 2008 No-Project Scenario there is little to no change in groundwater storage. Therefore, the hydrologic assumptions used for this EIR for modeled existing conditions provide a conservative analysis of groundwater storage (Kennedy/Jenks 2012b).

TABLE 5.16-2
Modeled Annual Average Groundwater Budget for the Westside Groundwater Basin under Modeled Existing Conditions

Inflow and Outflow Categories	Modeled Average Annual Inflow and Outflow Values (acre-feet per year [afy])[(a)]
Inflow from Surface Water to Groundwater	
Rain and irrigation water	14,034
Seepage from Lake Merced	846
Seepage from Golden Gate Park lakes	551
Inflow from San Francisco Bay and Ocean	12
Outflow from Groundwater to Surface Water	
Pumping of municipal and irrigation wells	-10,814
Outflow to San Francisco Bay and Ocean	-4,172
Seepage to Lake Merced	-960
Other Outflows	-94
Total	**-597**

Source: Kennedy/Jenks 2012b

Note:

(a) In this table, positive values represent water flowing into the groundwater basin (inflows), and negative values represent water flowing out of the groundwater basin (outflows).

Subsidence

Land subsidence is a gradual settling or sudden sinking of the Earth's surface due to subsurface movement of earth materials (Galloway et al. 1999). Land subsidence due to groundwater pumping can occur when groundwater levels are lowered and water drains out of clay layers that are within or between aquifers.

Subsidence can damage infrastructure, including pipelines, bridges, roads, railroads, and buildings, by causing them to crack during settling. Subsidence can also increase flooding or change drainage patterns by lowering the ground surface.

Subsidence either has not occurred in the Westside Groundwater Basin or insufficient monitoring information exists to document its occurrence (Fugro 2012b). No subsidence has been observed in land overlying the Westside Groundwater Basin, even though historical groundwater pumping has lowered the groundwater levels in portions of the Basin more than 200 feet (Fugro 2012b). Since the mid-1970s, pumping in the Westside Groundwater Basin has been between 6,000 and 8,000 acre-feet per year (afy) (LSCE 2010). These lowered groundwater levels from previous pumping have apparently not triggered any recognizable level of subsidence.

Groundwater Quality

Groundwater monitoring indicates that groundwater quality in the Westside Groundwater Basin generally meets drinking water standards according to the Maximum Contaminant Levels (MCLs) of the primary and secondary drinking water standards set by the California Department of Public Health (CDPH), with the exception of nitrate and volatile organic compounds (VOCs) in specific areas, and other secondary constituents in specific areas (i.e., pH, color, hardness, turbidity, conductivity, total dissolved solids [TDS], sulfate, chloride, manganese, and iron) (Kennedy/Jenks 2012e, Kennedy/Jenks 2012g). Refer to Section 5.16.2 (Regulatory Framework) for a discussion of primary and secondary drinking water standards, MCLs, and fluoridation.

Table 5.16-3 (Range of Existing Ambient Groundwater Quality for Selected Constituents in the Westside Groundwater Basin) provides the range of existing water quality for selected constituents from 2002 to 2011, as identified in the SFPUC 2011 annual monitoring report, together with the primary and secondary MCLs for these constituents, if they have been established. (SFPUC 2012e)

TABLE 5.16-3

Range of Existing Ambient Groundwater Quality for Selected Constituents in the Westside Groundwater Basin (mg/L)[(a), (b)]

Constituent	Range of Existing Water Quality[(c),(d)]		Primary MCL	Secondary MCL
	North Westside Groundwater Basin	South Westside Groundwater Basin		
Chloride	15 to 393	20 to 14,000	None	250
Iron	Non-detect to 5.07	Non-detect to 14.7	None	0.3
Manganese	Non-detect to 0.63	Non-detect to 1.71	None	0.05
Nitrate (as NO_3)	Non-detect to 65	Non-detect to 140	45	None
Sulfate	0.8 to 122	Non-detect to 1,200	None	250
Total Dissolved Solids (TDS)	129 to 1,305	128 to 21,200	None	500

Source: SFPUC 2012e

Notes:

(a) mg/L is milligrams per liter.

(b) Groundwater from municipal wells located in areas with higher nitrate concentrations is blended with SFPUC surface water prior to distribution; the resulting blend fully meets all Primary MCLs and Secondary MCLs (Kennedy/Jenks 2012e, Daly City 2012). Sample results are taken from throughout the Westside Groundwater Basin including shallow monitoring wells and monitoring wells adjacent to San Francisco Bay. Sample results do not include the Thornton Beach Monitoring Well or Fort Funston Monitoring Well located west of the Serra Fault, because those monitoring wells are not indicative of water quality in the central part of the Basin where the proposed Project would be located.

(c) Sample results reported as anomalous or questionable in the 2011 Annual Monitoring Report (SFPUC 2012e) were not included in the range of existing water quality.

(d) Sample results are from 2000 to 2011.

Monitoring data indicate isolated occurrences of elevated nitrate concentrations in groundwater above the primary drinking water MCL of 45 mg/L in portions of Daly City and South San Francisco, but not in the Colma or San Bruno areas. The extent of nitrate concentrations may at least be partially attributed to past agricultural fertilizer applications and possibly to past confined animal facilities such as stockyards. In the Daly City area, data available since 2000 show nitrate concentrations ranging up to 131 mg/L, but most sampling indicated concentrations range from 20 to 50 mg/L in supply wells perforated in the Primary Production Aquifer. In the South San Francisco area, data since 2000 show nitrate concentrations ranging up to 120 mg/L, with most sampling indicating concentrations from 40 to 80 mg/L in the upper portion of the Primary Production Aquifer. In the lower portion of the Primary Production Aquifer, nitrate concentrations decrease, often to levels at or below 1 mg/L (Kennedy/Jenks 2012e). (Note that groundwater from municipal wells located in areas with higher nitrate concentrations is blended with

SFPUC surface water prior to distribution; the resulting blend fully meets all drinking water standards (Kennedy/Jenks 2012e; Daly City 2012).

Based on sampling results, common contaminants, such as volatile organic compounds (VOCs), have rarely been found in the Primary Production and Deep Aquifers in the Westside Groundwater Basin (Kennedy/Jenks 2012e, Kennedy/Jenks 2012g). In a few cases, contaminants have reached groundwater, and the constituents have been detected in the shallow water-bearing zones approximately 30 to 50 feet below ground surface. The shallow water-bearing zones are underlain by low permeability fine-grained materials, separating the shallow zones from the Primary Production and Deep Aquifers. (Kennedy/Jenks 2012e)

The VOCs tetrachloroethylene (PCE) and trichloroethylene (TCE) have been detected in the Primary Production and Deep Aquifers at monitoring wells near Sites 1 and 11 in samples taken approximately 240 to 580 feet below ground surface. The source of the VOCs has not been identified (Kennedy/Jenks 2012g). In October 2012, the monitoring wells at Sites 1 and 11 were resampled. No VOCs were detected at Site 1, indicating that the earlier detections may not be representative of groundwater quality at Site 1 (SFPUC 2013c). VOCs were detected at Site 11, and the potential presence of these VOCs is under review by the SFPUC.

Information on the quality of groundwater in the South Westside Groundwater Basin is also available from the studies performed as part of the Groundwater Ambient Monitoring and Assessment (GAMA) program. The GAMA program is a comprehensive assessment of statewide groundwater quality implemented by the State Water Resources Control Board (SWRCB) in coordination with the U.S. Geological Survey (USGS) and Lawrence Livermore National Laboratory. The South Westside Groundwater Basin was included in a 2007 GAMA study as part of the investigation of the San Francisco Bay study unit, which includes portions of San Francisco, San Mateo, Santa Clara, and Alameda counties. Between April and June of 2007, the GAMA program included an assessment of groundwater quality in the San Francisco Bay study unit through sampling of 79 wells, 11 of which were located in or near the South Westside Groundwater Basin. (Ray et al. 2009)

As part of the GAMA study, groundwater samples were analyzed for a large number of organic constituents, including VOCs, pesticides, pharmaceutical compounds, and potential wastewater-indicator compounds. Groundwater samples were also analyzed for constituents of special interest (perchlorate and N-nitrosodimethylamine [NDMA]), naturally occurring inorganic constituents (e.g., nutrients, major and minor ions, trace elements), and radioactive constituents and microbial indicators.

The study was designed to provide an assessment of untreated groundwater quality. Although regulatory thresholds apply to treated water rather than untreated groundwater, in order to provide some context for the groundwater results, the GAMA report compared the concentrations of constituents measured in the untreated groundwater with regulatory limits. (Ray et al. 2009)

VOCs were detected in five of the 11 wells within the South Westside Groundwater Basin. All of the detections of VOCs were below health-based[7] thresholds, and most were less than one-tenth of the threshold values. Pesticides, pharmaceutical compounds, and wastewater indicator compounds were not detected in any of the 11 wells within the South Westside Groundwater Basin. Perchlorate was detected in seven of the 11 wells and NDMA in four of the wells. All detections of perchlorate and NDMA were below established thresholds. (Ray et al. 2009)

5.16.1.4 Groundwater-Surface Water Interactions

Lake Merced

This 300-acre freshwater lake is the largest freshwater lake in San Francisco and is composed of four individual, but connected, water bodies (North Lake, South Lake, East Lake, and Impound Lake). Lake Merced is located in southwestern San Francisco, approximately 0.25 mile east of the Pacific Ocean (see Figure 5.16-1 [Surface Water Hydrology]). The lake is incised into the upper portion of the Shallow Aquifer and is hydraulically connected to that aquifer (see Figure 5.16-2 [North-South Geologic Cross Section, Westside Groundwater Basin]) (Kennedy/Jenks 2012d). Previous investigations have shown that the lake is essentially an exposed part of the water table that defines the upper boundary of the Shallow Aquifer (LSCE 2002; 2004).

North and East Lakes, which are joined by way of a narrow channel, are almost completely separated from South Lake by natural or constructed barriers; however, a conduit connects South and North Lakes at an elevation of 3.35 feet City Datum[8]. Therefore, when the lake level drops below the conduit, North and South Lakes no longer have direct hydraulic connection and typically exhibit different lake levels. When the lake elevation in North and South Lakes is sufficiently higher than the bottom of the conduit, i.e., approximately 4 feet City Datum, water can freely flow through the conduit between the two lakes. South and Impound Lakes are also partially separated by a low berm; flow between these lakes is restricted below an elevation of approximately 4.3 feet. (Kennedy/Jenks 2012d)

Lake Merced does not currently have a natural outlet to the Pacific Ocean, but discharges instead to the Vista Grande Drainage Canal, which is a Daly City stormwater channel that serves a 2.5-square-mile basin within Daly City and which discharges to the Pacific Ocean in the vicinity of Fort Funston (Daly City 2011). Lake Merced discharges to the Vista Grande Drainage Canal at a spillway located near the

[7] The GAMA study refers to "health-based" thresholds which include thresholds promulgated by the U.S. EPA and the CDPH, including primary MCLs, Action Levels, Notification Levels, Treatment Techniques, Lifetime Health Advisory Levels, and Risk Specific Dose 5 Levels.

[8] City Datum is a measurement system that has been used at Lake Merced since at least 1926 and is used throughout this document for Lake Merced water levels. The City Datum does not represent the depth of the lake. An elevation of 0 feet City Datum is equal to 11.37 feet above mean sea level (NAVD 88) and 8.57 NGVD 29. Since mean sea level is equivalent to 0 feet NGVD 29, a lake level of -8.57 City Datum is equal to mean sea level, and negative lake elevations above this level are not below mean sea level.

midpoint of the southwest bank of South Lake at an elevation of 13 feet City Datum (Kennedy/Jenks 2012d). The spillway is a 30-inch-diameter pipe that connects to the existing Daly City Tunnel immediately downstream of the tunnel connection to the Vista Grande Drainage Canal. This spillway limits the operational level of the lake to 13 feet City Datum.

The bottom elevation of each individual lake varies. The bottom of the two largest lakes, South Lake and North Lake, are at elevations of approximately -17 and -15 feet City Datum, respectively (EDAW/Talavera & Richardson 2003). East Lake and Impound Lake are smaller and shallower; the bottoms of these lakes are at elevations of approximately -11 and -6 feet City Datum, respectively.

Existing Uses of Lake Merced

Lake Merced supports numerous recreational activities, including boating and fishing as well as other uses managed by the San Francisco Recreation and Park Department (SFRPD), as described in Section 5.11, Recreation. The SFPUC also maintains Lake Merced as a nonpotable emergency water supply for the City to be used for firefighting or sanitation purposes if no other sources of water are available (SFPUC 2011a). In the event of a major disaster (i.e., catastrophic earthquake), Lake Merced water could be pumped into the City's drinking water distribution system to maintain firefighting, basic sanitary (e.g., toilet flushing), and other critical needs. In the event of such an emergency, residents would be directed to boil tap water before consuming it.

Historical Water-level Fluctuations and Water Additions

Historically, Lake Merced was fed by a combination of groundwater, surface water from local streams and springs, direct precipitation, and occasional saltwater inputs from the ocean. Urbanization during the 1900s resulted in the development of the lake's watershed, which rerouted streams out of the lake and closed it off from the ocean. The lake has historically experienced water-level declines due to rerouting of the natural streams and springs; closing the lake off from the ocean; diversions of stormwater runoff to the City's combined sewer system that previously discharged to the lake; drought conditions; and regional and local groundwater pumping. Increases in the amount of impervious surfaces within San Francisco have also reduced natural recharge to the Shallow Aquifer. Lake Merced is now replenished primarily by direct precipitation, limited runoff from immediate adjacent areas, periodic overflows of the Vista Grande Drainage Canal, and shallow groundwater inflows. As a result, lake levels are sensitive to annual changes in precipitation and can be slow to recover from drought conditions.

Prior to 1935 (before the completion of the Hetch Hetchy water system), the lake was used for municipal water supplies. Lake levels typically ranged from -10 to 0 feet City Datum, but increased to over 13 feet City Datum by the late 1930s and early 1940s after water deliveries from the Hetch Hetchy water system began. However, water levels began to decline again in the 1940s. During the 1940s to late 1950s, lake elevations varied between 8 and 13 feet City Datum. Between the late 1950s and early 1980s, lake levels experienced a long-term declining trend, with lake elevations ranging between 4 and 10 feet City Datum. The reasons for the overall decline in lake levels between the 1950s and 1980s are reported to be drought, increased municipal groundwater pumping in the Westside

Groundwater Basin, and diversion of runoff into the City's combined sewer system due to increased urbanization. (Kennedy/Jenks 2012d)

During the late 1980s and early 1990s, Lake Merced water levels declined well below historical averages. The lowest water level observed was about -3.2 feet City Datum in 1993 after the major drought of the late 1980s and early 1990s. Since that time, the lake levels have steadily risen as a result of above-average precipitation, SFPUC water additions to the lake between 2002 and 2005, reduced irrigation pumping at the Lake Merced-area golf courses as a result of recycled water deliveries, and reduced municipal groundwater pumping as a result of the SFPUC's In-lieu Recharge Demonstration Study (see Figure 5.16-5 [Historic Lake Merced Water Levels]). Since 2006, lake levels have consistently remained between about 5 and 7 feet City Datum. In 2009, the lake level ranged from approximately 4.9 to 6.9 feet City Datum. As of June 2009, the lake level was 5.7 feet City Datum. (Kennedy/Jenks 2012d)

Groundwater Interactions

As stated above, Lake Merced is incised in the Shallow Aquifer, and the lake surface is essentially considered an exposed part of the water table. This hydraulic connection was further demonstrated by groundwater monitoring conducted during the SFPUC's water additions in 2002 and 2003, when 70 to 80 percent of the volume of water additions contributed to lake storage and the remaining 20 to 30 percent contributed to the net outflow to groundwater and evaporative losses during the water addition periods. (Kennedy/Jenks 2012d)

Currently, the direction of groundwater flow in the unconfined Shallow Aquifer in the vicinity of, and north of, Lake Merced is predominantly toward the west. However, in the southern portion of Lake Merced, groundwater flow in this aquifer is more to the southwest. The general direction of groundwater flow in the underlying Primary Production Aquifer exhibits a more pronounced north-to-south flow direction from the southern portion of the Lake Merced area towards the Daly City area, probably due to greater pumping stresses in these aquifers to the south. This results in lower groundwater levels in the Shallow Aquifer at the southern portion of Lake Merced, indicating that there is a higher net outflow of lake water to the groundwater in South and Impound Lakes, and more inflow of groundwater to Lake Merced in North and East Lakes. (Kennedy/Jenks 2012d)

A 2009 aquifer test conducted on the Lake Merced Pump Station Test Well, completed in the Primary Production Aquifer, demonstrated that in the vicinity of Lake Merced, the lowermost portion of the Primary Production Aquifer exhibits characteristics of a confined aquifer (Kennedy/Jenks 2012d). The aquifer test also demonstrated that the Shallow Aquifer is unconfined and hydraulically separated from the lowermost portion of the Primary Production Aquifer by multiple confining layers.

Lake Merced Water Quality

Regulatory Considerations

As described in more detail in Section 5.16.2 (Regulatory Framework), the RWQCB has identified the following existing beneficial uses for Lake Merced: body-contact recreation (fishing), noncontact recreation, warm freshwater habitat, cold freshwater habitat, fish spawning, and wildlife habitat. Potential beneficial uses include municipal and domestic supplies. The RWQCB has established water quality objectives that are designed to be protective of beneficial uses. In addition, in 2007, the RWQCB listed Lake Merced as an impaired water body for dissolved oxygen and pH because of a listing made by the U.S. EPA (SWRCB 2011), despite a request by the SFPUC not to list Lake Merced based on existing water quality data (RWQCB 2009a). The listing does not identify a source for the impairment.

SFPUC's Existing Water Quality Monitoring Program

To monitor lake health, the SFPUC monitors a broad range of water quality constituents at various depths within Lake Merced on a quarterly basis at four locations: North, Northeast, South–Pistol Range, and South–Pump Station (Kennedy/Jenks 2010a). The sampling is conducted between three and eight times per year, but is typically conducted quarterly. For the majority of the parameters, samples at each location are collected at various depths, starting at the lake surface, and decreasing at five-foot intervals to the lake bottom. Table 5.16-4 (Lake Merced Water Quality Data and Basin Plan Water Quality Objectives) shows the range of values for each constituent measured between 1997 and 2009, as well as the corresponding water quality objectives provided in the *Water Quality Control Plan for the San Francisco Bay Basin* (Basin Plan, further discussed under Section 5.16.2 [Regulatory Framework]). A previous water quality evaluation (Kennedy/Jenks 2010a) identified seven water quality parameters that represent lake health; these parameters can be grouped as follows:

- Dissolved oxygen, which is required for fish habitat and healthy biological processes.
- Secchi depth, which is a measurement of lake clarity, and can be affected by algae production and suspended solids.
- Algae, total available nitrogen and nitrogen-to-phosphorous ratio (N:P), which are indicators of algal production and nutrients, both of which affect long-term lake health.
- Total coliform and Escherichia coli (E. coli), both of which are indicators of pathogenic microorganisms and fecal contamination.

Based on a review of these parameters, the previous water quality evaluation (Kennedy/Jenks 2010a) determined that the water quality of Lake Merced remained relatively constant from 1997 to 2009 and that there was a slight improvement in lake clarity (secchi depth). Also, during the 1997 to 2009 sampling period, no substantial changes in algal biomass levels occurred, although there were periodic increases in concentration due to algae blooms. Dissolved oxygen levels remained above the warmwater habitat criterion of 5 mg/L and the coldwater habitat criterion of 7 mg/L for the majority of the data set. However, dissolved oxygen levels were determined to be affected by periods of weak stratification[9], and there were episodes of dissolved oxygen lower than 5 mg/L during the summer and late fall in the deeper portions of the lake. Average pH levels never exceeded the freshwater criterion of 8.5 during the 1997 to 2009 sampling period.

TABLE 5.16-4
Lake Merced Water Quality Data and Basin Plan Water Quality Objectives

Parameter	Units	Range in Values, 1997 – 2009	Basin Plan Water Quality Objective
Algal biomass	Micrograms per liter (µg/L)	402-6,705	Waters shall not contain biostimulatory substances such as nitrogen and phosphorous in concentrations that would promote aquatic growths to the extent that the growths would cause nuisance or adversely affect beneficial uses. Adverse effects are indicated by irregular and extreme levels of chlorophyll a or phytoplankton blooms.
Alkalinity	mg/L	136-230	None
Ammonium	mg/L	Not detected to 0.65	None
Bromide	mg/L	0.22-0.34	None
Chloride	mg/L	58-98	Controllable water quality factors shall not increase the total dissolved solids or salinity of the water so as to affect any designated beneficial uses, particularly fish migration and estuarine habitat.
Chlorophyll	µg/L	4.7-100	Waters shall not contain biostimulatory substances such as nitrogen and phosphorous in concentrations that would promote aquatic growths to the extent that the growths would cause nuisance or adversely affect beneficial uses. Adverse effects are indicated by irregular and extreme levels of chlorophyll a or phytoplankton blooms.
Specific conductance	µmhos/cm	431-715	Controllable water quality factors shall not increase the total dissolved solids or salinity of the water so as to affect any designated beneficial uses, particularly fish migration and estuarine habitat.

[9] Lake stratification is the separation of a lake into layers. The amount of lake stratification can vary over the day, as well as seasonally, depending on a number of factors.

TABLE 5.16-4
Lake Merced Water Quality Data and Basin Plan Water Quality Objectives

Parameter	Units	Range in Values, 1997 – 2009	Basin Plan Water Quality Objective
Dissolved oxygen	mg/L	0.1-12.2	• Warmwater habitat: 7.0 mg/L • Coldwater habitat: 5.0 mg/L • The median dissolved oxygen level shall not be less than 80 percent saturation for three months.
E. Coli	CFU/100 mL	2.0-100	• Moderately used areas: 298 • Lightly used areas: 406 • Infrequently used areas: 576
Fluoride	mg/L	0.22-0.68	None
Hardness	mg/L	140-230	None
Iron	mg/L	Not detected to 0.14	None
Lead	µg/L	0.03-0.81	4-day average: 2.5 1-hour average: 2.4
Manganese	mg/L	0.02-0.3	None
MTBE	µg/L	Not detected to 1.9	None
Nitrate	mg/L	Not detected to 0.62	Waters shall not contain biostimulatory substances such as nitrogen and phosphorous in concentrations that would promote aquatic growths to the extent that the growths would cause nuisance or adversely affect beneficial uses. Adverse effects are indicated by irregular and extreme levels of chlorophyll a or phytoplankton blooms.
Orthophosphate	mg/L	Not detected to 0.2	Waters shall not contain biostimulatory substances such as nitrogen and phosphorous in concentrations that would promote aquatic growths to the extent that the growths would cause nuisance or adversely affect beneficial uses. Adverse effects are indicated by irregular and extreme levels of chlorophyll a or phytoplankton blooms.

TABLE 5.16-4
Lake Merced Water Quality Data and Basin Plan Water Quality Objectives

Parameter	Units	Range in Values, 1997 – 2009	Basin Plan Water Quality Objective
Oxidation-reduction potential	mV	29-543	None
pH	–	6.8-8.8	• The pH shall not be depressed below 6.5 or raised above 8.5. • Controllable water quality factors shall not cause changes greater than 0.5 units in normal ambient pH levels.
Plankton	NU/mL	17-2,511	Waters shall not contain biostimulatory substances such as nitrogen and phosphorous in concentrations that would promote aquatic growths to the extent that the growths would cause nuisance or adversely affect beneficial uses. Adverse effects are indicated by irregular and extreme levels of chlorophyll a or phytoplankton blooms.
Secchi depth (lake clarity)	feet	1.0-3.0	None
Sulfate	mg/L	6.5-16	None
Temperature	°F	50-72	The temperature of any coldwater or warmwater freshwater habitat shall not be increased by more than 5 °F above the natural receiving water temperature.
Total coliform	MPN/100 mL	109-2,420	• Municipal Supply: geometric mean less than 100 • Water Contact Recreation: median less than 240 and no sample greater than 10,000
Total dissolved solids	mg/L	276-458	Controllable water quality factors shall not increase the total dissolved solids or salinity of the water so as to affect any designated beneficial uses, particularly fish migration and estuarine habitat.
Total Kjeldahl nitrogen	mg/L	Not detected to 28.2	Waters shall not contain biostimulatory substances such as nitrogen and phosphorous in concentrations that would promote aquatic growths to the extent that the growths would cause nuisance or adversely affect beneficial uses. Adverse effects are indicated by irregular and extreme levels of chlorophyll a or phytoplankton blooms.

TABLE 5.16-4
Lake Merced Water Quality Data and Basin Plan Water Quality Objectives

Parameter	Units	Range in Values, 1997 – 2009	Basin Plan Water Quality Objective
Total organic carbon	mg/L	Not detected to 16.4	None
Total phosphorous	mg/L	Not detected to 0.26	Waters shall not contain biostimulatory substances such as nitrogen and phosphorous in concentrations that would promote aquatic growths to the extent that the growths would cause nuisance or adversely affect beneficial uses. Adverse effects are indicated by irregular and extreme levels of chlorophyll a or phytoplankton blooms.
Turbidity	NTU	2.5-33	Increases from normal background light penetration or turbidity relatable to waste discharge shall not be greater than 10 percent in areas where natural turbidity is greater than 50 NTU.

Lake Level Water Quality Analysis Conducted for the EIR

Existing water quality data from 1997 to 2009 were reviewed as part of this EIR analysis to identify any potential relationships between lake levels, stratification, and water quality. This analysis considered water quality data collected at various depths (lake surface, 10-foot depth, and lake bottom) and compared the data to lake levels at the time of sampling. During the monitoring period, lake levels ranged from approximately 0 to 7 feet City Datum, with the minimum level of 0 feet City Datum occurring in 1998 and 2003, prior to conducting the In-lieu Recharge Demonstration Study discussed above. The analysis focused on the following constituents and processes, as they are the primary drivers of ecosystem health, eutrophication,[10] biogeochemistry,[11] and the suitability of the lake for the Basin Plan's identified beneficial uses of freshwater habitat, recreation, and, potentially, municipal water supply:

- **Dissolved oxygen:** Dissolved oxygen is critical to the survival of aquatic species such as fish and invertebrates, and is an indicator of the lake's overall ecological health. Dissolved oxygen is affected by (and can in turn affect) a broad range of drivers such as external pollution inputs, internal loads of certain nutrients, mixing, and primary production[12] (described below). Low dissolved oxygen levels limit habitat for aquatic organisms and can contribute to internal nutrient loading (the release of ammonia, orthophosphates, and other compounds) from bottom sediments.
- **Algal biomass and chlorophyll:** Algal biomass and chlorophyll are indicators of the levels of primary productivity in the lake. Primary productivity is the conversion of inorganic nutrients such as nitrogen and phosphorus into organic biomass through uptake by organisms such as algae and cyanobacteria. Algae and other primary producers can increase dissolved oxygen during the day due to photosynthesis, and take up dissolved oxygen at night through respiration. In addition, the decomposition of dead algae uses dissolved oxygen and can exacerbate eutrophication.
- **Secchi depth:** Secchi depth is an indicator of turbidity (i.e., the cloudiness of the water) that can also be empirically linked to algal biomass/chlorophyll concentrations. Low secchi depths (high turbidity) can indicate the presence of organic and inorganic suspended solids that influence dissolved oxygen and nutrient levels. In general, areas with low secchi depths are considered aesthetically unappealing.
- **Nitrogen and phosphorus:** Nitrogen and phosphorus are the main nutrients that drive eutrophication and primary production in Lake Merced. They enter the lake primarily through external stormwater and internal nutrient cycling. Previous studies have shown that groundwater inflow to the lake introduces significant amounts of nitrogen (Yates et al. 1990). High levels of nitrogen and phosphorus can contribute to blooms of algae and cyanobacteria within a lake. At Lake Merced, nitrogen is measured as nitrate, ammonia/ammonium, and total Kjeldahl nitrogen (the sum of organic nitrogen and ammonia/ammonium). This analysis focuses on inorganic nitrogen (nitrate and ammonia/ammonium). Phosphorus at Lake Merced is measured as orthophosphate and total phosphorus; the former is considered in this analysis.

---

[10] The process by which a body of water acquires a high concentration of nutrients, especially phosphates and nitrates, which can promote excessive growth of algae.

[11] The scientific discipline that involves the study of the chemical, physical, geological, and biological processes and reactions that govern the composition of the natural environment.

[12] Primary production is the production of organic matter from inorganic carbon sources, generally through photosynthesis. Through the process of photosynthesis, plants, and algae in lakes capture energy from light and use it to combine carbon dioxide and water to produce carbohydrates and oxygen.

- **pH:** The pH of a water body describes its acidity or alkalinity on a scale of 0 to 14, where 7 is neutral. Water bodies with a pH of less than 7 are acidic and water bodies with a pH above 7 are alkaline or basic. The pH level is influenced by a broad range of factors, including basin geology, watershed runoff, bacterial respiration/decomposition of organic matter, and primary productivity (more productive ecosystems tend to have higher pH levels).

The EIR investigation focused on three constituents, dissolved oxygen, orthophosphate, and ammonia, to evaluate whether lower lake levels would lead to decreased (less frequent, weaker, shorter in duration) stratification and increased mixing within the lake (see Appendix K [Lake Merced Water Quality Data and Graphs]). Increased mixing affects water quality in two primary ways:

- It brings surface water with generally higher dissolved oxygen levels into contact with hypoxic (less than 5 mg/L dissolved oxygen) or anoxic (less than 2 mg/L dissolved oxygen) bottom sediments. This contact can help form an oxygenated layer on the bottom sediments and biogeochemically "seal" them off from the water column, minimizing the release of nutrients such as ammonia and orthophosphate from sediments into the lake. The release of nutrients from bottom sediments is called "internal nutrient loading," and it can have a substantial effect on water quality within lakes, ponds, and reservoirs.
- It brings bottom water that has been in contact with sediments up to the surface into the photic zone[13], where any nutrients released from bottom sediments due to internal nutrient loading can fuel the growth of phytoplankton blooms. These blooms can exacerbate the process of eutrophication and create a positive feedback loop that results in further degradation of water quality.

In summary, this investigation indicated that from 1997 through 2009 there appeared to be no substantial correlations between the depth of Lake Merced and the indicator water quality parameters evaluated. While a depth threshold for Lake Merced water quality may exist (i.e., a depth below which water quality consistently and significantly decreases), none of the depths recorded from 1997 through 2005 appeared to represent such a threshold for the constituents analyzed. It is likely that factors external to Lake Merced are largely driving water quality or are, at the very least, a more dominant driver than lake level on its own. Specifically, the magnitude, duration, frequency, and characteristics (e.g., pollutants, dissolved oxygen demand) of urban runoff to the lake – from either the local watershed or the Vista Grande Drainage Canal – likely play a major role in introducing nutrients and other pollutants that can drive water quality impacts. Shallow, urban lakes such as Lake Merced tend to be strongly influenced by episodic events such as storms and wind events as well as more regular events such as urban runoff. While lake level is an important factor, it is likely that these factors have a relatively greater influence on water quality within Lake Merced than lake levels.

[13]The upper layer of water of a body, defined by the depth to which sunlight can penetrate to permit photosynthesis.

Pine Lake

Pine Lake is a relatively shallow 3.4-acre freshwater lake located in the westernmost portion of Stern Grove and Pine Lake Park, about 0.5 mile northeast of Lake Merced (Figure 5.16-1 [Surface Water Hydrology Map]). Like Lake Merced, Pine Lake is incised into the upper portion of the Shallow Aquifer. Although records pertaining to Pine Lake were limited until the past 10 to 15 years, it has been reported that in the 1930s as much as one-third of the total lake was filled at the eastern end to accommodate additional park development. (Kennedy/Jenks 2010d)

Historically, Pine Lake has received inflows from precipitation and stormwater runoff, and the primary outflows have been evapotranspiration and groundwater outflows (Kennedy/Jenks 2012d). Over time, the lake has become shallower; in the early 1900s, the depth of the lake was reportedly about 20 feet deep. During a period of low lake levels in the early 2000s, maximum depths were only 7 to 8 feet. In 2004, the lake level was reported to be very low, at an elevation of 33.5 feet, pursuant to the National Geodetic Vertical Datum of 1929 (NGVD 29)[14], or 3 to 5 feet deep. The historical change in Pine Lake levels has been attributed to a combination of long-term sedimentation and local declines in groundwater levels. It is also likely that intense urbanization in the area surrounding Pine Lake reduced the amount of natural inflow to the lake (Kennedy/Jenks, 2012d). Pine Lake is primarily a scenic resource used for recreational purposes (i.e., aesthetic enjoyment) and has never been used as a drinking water supply.

The SFRPD has conducted studies and implemented several projects under its capital improvement program to address declining water levels and ecological issues at Pine Lake. As part of these efforts, the SFRPD eradicated invasive plants in 2007 and replaced them with native vegetation. In addition, the SFRPD installed a new pump in the Stern Grove well and constructed a six-inch-diameter pipe from the well to an outlet channel that drains to Pine Lake, with the goal of maintaining lake levels at a water elevation of 40.1 feet NGVD 29. This elevation is about 4 feet higher than average historical lake levels, and about 7 feet higher than the lake level in 2004. (Kennedy/Jenks 2012d)

Lake levels in Pine Lake are currently maintained at the desired water elevation (i.e., 40.1 feet NGVD 29) with groundwater input from the Stern Grove well, which has resulted in a lake depth of about 10 to 12 feet NGVD 29. The Stern Grove well is 270 feet deep and draws water from the Primary Production Aquifer. Based on information from the SFRPD, this well is operated approximately three to four times each year to maintain Pine Lake water levels. At that pumping rate and operational duration, the total amount of water added to Pine Lake to maintain water levels is approximately 4.8 afy (Kennedy/Jenks

---

[14] Groundwater elevations are commonly referenced to the North American Vertical Datum of 1988 (NAVD 88) and/or the National Geodetic Vertical Datum of 1929 (NGVD 29). NAVD 88 was established in 1991 and is the most up-to-date and accurate datum. NGVD 29 was used by surveyors and engineers for most of the 20th century and is 2.8 feet lower than NAVD 88 in San Francisco and northern San Mateo County. The technical reports prepared in support of the GSR Project used both datums; therefore, for consistency, this EIR uses the same datum employed in a given technical report when discussing information obtained from that report. Mean sea level is equivalent to 0 feet NGVD 29, which is also equivalent to 2.8 feet NAVD 88.

2012d). The SFRPD continues to use groundwater from the Stern Grove well to augment water levels in Pine Lake as part of its long-term goal of maintaining the water level at 40.1 feet NGVD 29.

Groundwater Interactions and Lake Levels

Shallow Aquifer groundwater levels in the vicinity of Pine Lake are monitored in two nearby monitoring wells: LMMW-5SS and LMMW-5S (Kennedy/Jenks 2012d). Monitoring well LMMW-5SS (shallow well adjacent to Pine Lake and screened between 38 and 48 feet below ground surface) was designed to monitor the uppermost groundwater zone in the Shallow Aquifer near Pine Lake, and measurements from this well can be used to infer water levels in Pine Lake. Since 2002, groundwater elevations in this well have typically ranged from 37 to 40 feet NGVD 29. However, during periods of low levels in Pine Lake, groundwater levels in this well declined to about 33 feet NGVD 29 (Kennedy/Jenks May 2012d). Variations in groundwater elevations measured in this well appear to closely approximate changes in water levels in Pine Lake.

Monitoring well LMMW-5S, which is screened between 65 and 85 feet below ground surface in the Shallow Aquifer, is also designed to monitor groundwater levels in the Shallow Aquifer near Pine Lake. However, this well monitors water from deeper within the Shallow Aquifer than does LMMW-5SS, and may be separated from the shallower portions of the aquifer by a clay layer. Generally, groundwater levels in LMMW-5SS are about 1 to 4 feet higher than those observed in LMMW-5S (Kennedy/Jenks, 2012d). Pine Lake levels can also be inferred to be slightly higher than groundwater levels in LMMW-5S. The Stern Grove well pumps groundwater from the Primary Production Aquifer, below the clay aquitard[15] that forms the base of the Shallow Aquifer; pumping from this well is not considered to directly affect shallow groundwater levels near Pine Lake. (Kennedy/Jenks 2012d)

As part of the studies discussed above, the SFRPD added approximately 14 af of groundwater from the nearby Stern Grove well to Pine Lake in November 2004 to evaluate the potential use of the well to maintain Pine Lake at the design water level. During the test, groundwater levels in LMMW-5SS rapidly rose about 5 to 6 feet and leveled out at an elevation of 40.2 feet NGVD 29, which was near the lake elevation at that time, confirming that Pine Lake is in direct hydraulic connection with the shallower portion of the Shallow Aquifer. Groundwater levels in LMMW-5S rose less than 1 foot during the test and were about 8 feet lower than the lake level at the end of the test, thus confirming that direct hydraulic connection between the lake and the deeper parts of the Shallow Aquifer is limited (possibly due to an intervening clay layer) (Kennedy/Jenks 2012d). This limited hydraulic connection with the deeper parts of the Shallow Aquifer limits losses from Pine Lake to the aquifer and allows for maintenance of Pine Lake water levels with minimal water additions.

15 A semi-impermeable layer that confines an aquifer.

Golden Gate Park Lakes

Golden Gate Park is located over the northernmost part of the North Westside Groundwater Basin, approximately three miles north of the Lake Merced area. There are 13 lakes, ponds, or water features within Golden Gate Park in the northernmost extent of the Westside Groundwater Basin: Stow Lake, Spreckels Lake, North Lake, Lily Pond, Lloyd Lake, Elk Glen Lake, Metson Lake, Mallard Lake, South Lake, Middle Lake, Alvord Lake, Fly Casting Pools, and Rainbow Falls and Pond. The largest lakes are Stow, Spreckels, and North, with surface areas of approximately 13, six, and four acres, respectively (Kennedy/Jenks 2012d). The other lakes are smaller, ranging from about 0.2 to 0.5 acres in surface area. Alvord Lake, Fly Casting Pools, and Rainbow Falls and Pond are very small, with paved bottoms and fountains or falls; they are considered ornamental water features rather than lakes.

All of the Golden Gate Park lakes are either constructed or have been substantially altered by human activity. It is believed that Elk Glen, Middle, and North Lakes were originally natural groundwater-fed ponds that were deepened, while the other lake locations may or may not have coincided with preexisting natural surface water features. (Kennedy/Jenks 2012d)

The constructed Golden Gate Park lakes were excavated into the shallow soils approximately 100 years ago. Most of these lakes were constructed to a maximum depth of 5 feet; Elk Glen Lake was originally 7 feet deep. With subsequent accumulation of sediment in the lakes, the average depths by 1994 were about 1 foot shallower than originally constructed, except for the north portion of North Lake, which was deepened to approximately 9 to 10 feet in 1990.

Groundwater Conditions

As discussed above, the Shallow Aquifer is not present in this area. Rather, the Shallow and Primary Production Aquifers are merged because of the absence of the -100-foot clay layer in this area. Historically, shallow groundwater levels throughout most of Golden Gate Park have ranged from 40 to 60 feet below ground surface, but are as shallow as 14 to 15 feet below ground surface at the far western edge of Golden Gate Park, near the Pacific Coast. (Kennedy/Jenks 2012d)

Most of the lakes were constructed with a gravelly clay liner in an attempt to minimize leakage of lake water into the shallow soils. Lily Pond did not require this addition of material because it was constructed within an old shale quarry, and the existing gravelly clay bottom already minimized leakage. The natural lakes (Elk Glen, Middle, and North) have not been lined. A 1994 study determined that most of the Golden Gate Park lakes leak appreciable amounts of water, including those lined with clay materials. The study estimated that the combined leakage from the park lakes was about 0.5 mgd (1.5 af per day), with about 77 percent of the leakage coming from Elk Glen Lake, Middle Lake, and North Lake, which are the three natural lakes confirmed to be unlined (Kennedy/Jenks 2012d). Some of the water lost from the lakes is periodically made up by additions of groundwater pumped from the Elk Glen, South Windmill, and North Lake irrigation wells in Golden Gate Park, while the remainder is replenished by direct precipitation and stormwater runoff.

The average depths to groundwater in the Golden Gate Park area indicate that the shallow lakes do not intersect the groundwater table and are hydraulically separated from the groundwater. On the other hand, the lakes do recharge the aquifer through leakage to the shallow soils described above. However, this exchange is not considered a groundwater/surface water interaction because the water flows in one direction only, and the water table is too far below the bottom of the lakes for changes in groundwater levels to affect lake levels.

Colma Creek, San Bruno Creek, Millbrae Creek, and Lomita Channel

As is typical of surface water features located in heavily urbanized areas, much of the stream reaches of Colma Creek, San Bruno Creek, Millbrae Creek, and the Lomita Channel have been channelized, buried, and/or lined with impervious materials. Except for its upper reaches on San Bruno Mountain, all of historic Colma Creek and its tributaries have been diverted into engineered channels or underground storm drains. Similar alterations have also been made to San Bruno Creek and Millbrae Creek. These modifications have resulted in major changes to the natural hydrologic and ecologic processes that previously existed. In the portion of the South Westside Groundwater Basin where Colma Creek is located (except for the eastern area closer to the Bay), the depth to groundwater ranges from many tens to hundreds of feet below ground surface, due to drawdown of the groundwater caused by historic municipal pumping in the Daly City, South San Francisco, and San Bruno areas. Large production wells in these areas pump from the Primary Production and Deep Aquifers (the Shallow Aquifer is not present). Where the lower reaches of Colma Creek are located, in South San Francisco, the depth to groundwater is highly variable, depending largely on proximity to pumping wells and the depth of the aquifer being measured. (Kennedy/Jenks 2012d)

Where San Bruno Creek, Millbrae Creek, and the Lomita Channel are located (in San Bruno and Millbrae), the groundwater in the Primary Production Aquifer is typically at elevations ranging from -100 to -200 feet NGVD 29. However, in areas closer to the Bay, groundwater levels are in the range of approximately 10 to -30 feet NGVD 29. (Kennedy/Jenks 2012d)

Extensive modifications to Colma Creek, San Bruno Creek, the Lomita Channel and Millbrae Creek have effectively isolated almost all of the creek reaches from the underlying groundwater, precluding any substantial degree of groundwater-surface water interaction with the creeks. Furthermore, groundwater beneath much of Colma Creek is far below ground surface, further reducing the likelihood of direct groundwater-surface water interaction. Even where groundwater levels are relatively shallow in the southernmost portion of the South Westside Basin near the Bay, the heavy alteration of all three creeks (i.e., concrete lining) precludes exchanges between surface water and shallow groundwater. (Kennedy/Jenks 2012d)

Colma Creek is apparently in some degree of communication with shallow groundwater in its upper, least-altered reaches near San Bruno Mountain, because water use by stands of eucalyptus trees there is believed to deprive the creek of some baseflow. However, any shallow groundwater in this area exists in a highly localized system, far removed from the deeper groundwater of the Primary Production Aquifer, which exists at lower elevations in the Basin. Similar conditions are likely present for the unaltered upland portions of San Bruno Creek and Millbrae Creek. (Kennedy/Jenks 2012d)

5.16.2 Regulatory Framework

5.16.2.1 Federal and State Regulations

Clean Water Act

The federal Clean Water Act, enacted by Congress in 1972 and amended several times since, is the primary federal law regulating water quality in the United States and forms the basis for several State and local laws throughout the country. It was established to "restore and maintain the chemical, physical, and biological integrity of the Nations' waters." The Act established the basic structure for regulating discharges of pollutants into the waters of the United States. The Clean Water Act gave the U.S. EPA the authority to implement federal pollution control programs, such as setting water quality standards for contaminants in surface water, establishing wastewater and effluent discharge limits for various industry categories, and imposing requirements for controlling nonpoint-source pollution. At the federal level, the Clean Water Act is administered by the U.S. EPA and U.S. Army Corps of Engineers (USACE). At the state and regional levels in California, the act is administered and enforced by the State Water Resources Control Board (SWRCB) and the nine Regional Water Quality Control Boards (RWQCBs).

Drinking Water Regulations

U.S. Environmental Protection Agency/California Department of Public Health

The California Safe Drinking Water Act is implemented by the California Department of Public Health (CDPH) and provides that drinking water in the State shall not exceed primary and secondary Maximum Contaminant Levels (MCLs) (CDPH 2011). Primary and secondary MCLs for specific constituents are set in Title 22 of the California Code of Regulations (commonly referred to as simply "Title 22"). Primary MCLs are established to protect public health; secondary MCLs are established for contaminants that may cause the water to appear colored or taste or smell bad, causing people to stop using water from their public water system even though the water is safe to drink (U.S. EPA 2012b). The U.S. EPA also sets primary and secondary MCLs through its National Primary Drinking Water Regulations. California and federal MCLs are generally similar, although California's levels may be more stringent. MCLs are set for bacteria and other micro-organisms, chemicals and radionuclides. Title 22 also requires that public water systems with 10,000 service connections or more fluoridate their water supply to protect oral health; fluoride concentrations are specified by the regulations.

CDPH has also established Notification and Response Levels for 30 constituents for which no MCLs have been established. The Notification Levels are health-based advisory levels; public water systems must notify their customers annually if concentrations of these constituents exceed the Notification Level. The CDPH recommends removal of the drinking water source from service when concentrations of these constituents exceed Response Levels. (CDPH 2011)

After Project construction and prior to distribution of groundwater for domestic use, the CDPH would monitor water quality to confirm that primary and secondary MCLs are not exceeded at each connection point (MWH et al. 2008). California Environmental Protection Agency Office of Environmental Health Hazard Assessment (OEHHA) has set Public Health Goals at concentrations that pose no significant health risk if consumed for a lifetime. Public Health Goals may be more stringent than MCLs for certain constituents, because the CDPH must consider detectability, treatability, and cost of treatment, as well as health risk when setting MCLs.

Drinking Water Source Assessment and Protection Program

The State's Drinking Water Source Assessment and Protection (DWSAP) Program requires a Drinking Water Source Assessment to assess the potential for contamination and vulnerability of drinking water supplies (CDPH, Division of Drinking Water and Environmental Management 2000). The Assessment shows whether the source of the drinking water would be vulnerable to Potentially Contaminating Activities (PCA). If the source of drinking water would be vulnerable, a voluntary source water protection program is recommended. Source water protection is not a mandated element of the DWSAP program, but is required for a complete wellhead protection program and for permitting municipal supply wells and affords a public water system or community the opportunity to build on work performed for the drinking water source assessment.

The DWSAP for groundwater sources (i.e., wells) requires California drinking water purveyors to assess local hydrogeology, well construction and production, and land use in the vicinity of proposed water supply wells. These components are then used to delineate Groundwater Protection Zones for each well, which represent the area of groundwater that may be drawn in by the well in two (Zone A), five (Zone B5), and ten (Zone B10) years of pumping. The CDPH requires a minimum radius for each protection zone: 600 feet for Zone A, 1,000 feet for Zone B5, and 1,500 feet for Zone B10. Within these three Groundwater Protection Zones, PCAs are identified and evaluated.

Porter-Cologne Water Quality Control Act

The Porter-Cologne Water Quality Control Act is the primary statute covering the quality of waters in California. Under the act, the SWRCB has the ultimate authority over the State's water quality policy. The nine RWQCBs regulate water quality under this Act through the regulatory standards and objectives set forth in Water Quality Control Plans (also referred to as Basin Plans) prepared for each region.

Regional Water Quality Control Board, Beneficial Uses

The *Water Quality Control Plan for the San Francisco Bay Basin* (Basin Plan), prepared by the San Francisco Bay RWQCB, identifies the beneficial uses of surface waters and groundwater within its region to maintain the continued beneficial uses of the groundwater (RWQCB 2011). The RWQCB is responsible for protecting the beneficial uses of San Francisco Bay Area water resources, including water bodies in the Project area. The Basin Plan was last revised on December 31, 2011 (RWQCB 2011). The water bodies in the Project area that have designated beneficial uses include Lake Merced, San Francisco Bay, Colma Creek, and San Bruno Creek. The beneficial uses provide the basis for determining appropriate water quality objectives for these water bodies. The RWQCB has not assigned beneficial uses for the Vista Grande Drainage Basin, Twelve Mile Creek, Green Hills Creek, Lomita Channel, Highline Canal, Millbrae

Creek, or Pine Lake. Although there are no designated beneficial uses of Pine Lake, the lake is used primarily for noncontact recreational purposes (i.e., aesthetic enjoyment) in Pine Lake Park.

Table 5.16-5 (Designated Beneficial Uses of Surface Water Bodies in Project Area) lists the designated beneficial uses for water bodies in the vicinity of the proposed Project. Agricultural supply is identified as an existing beneficial use for groundwater in the Westside Groundwater Basin in San Francisco; municipal and domestic supply as well as industrial service supply and industrial process supply are listed as "potential" beneficial uses. Existing beneficial uses of Lake Merced identified in the Basin Plan include body contact recreation (e.g., fishing), noncontact recreation (e.g., rowing), warm freshwater habitat, cold freshwater habitat, fish spawning, and wildlife habitat. Municipal and domestic supplies are also potential beneficial uses of Lake Merced.

TABLE 5.16-5
Designated Beneficial Uses of Surface Water Bodies in Project Area

Water Body	Designated Beneficial Uses [(a)]
Lake Merced	COMM, COLD, SPWN, WARM, WILD, REC-1, REC-2, MUN (potential)
San Francisco Bay (Lower)	IND, COMM, SHELL, EST, MIGR, RARE, SPWN, WILD, REC-1, REC-2, NAV
Colma Creek	WARM, WILD, REC-1, REC-2
San Bruno Creek	WARM, WILD, REC-1, REC-2

Source: RWQCB 2011

Notes:

(a) Beneficial Uses Key: COLD (Cold Freshwater Habitat); COMM (Commercial Sport and Fishing); EST (Estuarine Habitat); IND (Industrial Service Supply); MUN (Municipal and Domestic Supply); NAV (Navigation); RARE (Rare, Threatened, or Endangered); REC-1 (Body Contact Recreation); REC-2 (Noncontact Recreation); SHELL (Shellfish Harvesting); SPWN (Fish Spawning); WARM (Warm Freshwater Habitat); WILD (Wildlife Habitat)

The RWQCB also oversees and regulates groundwater investigations, cleanup, and abatement activities at sites with identified pollution problems in accordance with Resolution No. 92-49 – Policies and Procedures for Investigation and Cleanup and Abatement of Discharged Under California Water Code Section 13304 (the resolution established procedural and substantive requirements that apply cleanups of waste). The RWQCB manages groundwater investigations through five main program areas:

- Spills, Leaks, Investigations, and Cleanups (SLIC) Program;
- UST Program;
- Landfill Program;
- Department of Defense/Department of Energy (DOD/DOE) Program; and
- Aboveground Petroleum Storage Tank Program.

The RWQCB approves soil and groundwater clean-up levels for polluted sites. The overall clean-up level established for a waterbody is based upon the most sensitive beneficial use identified. Soil clean-up levels for the unsaturated zone are established using guidance from the U.S. EPA, Department of Toxic Substances Control and OEHHA.

Federal Clean Water Act Section 401 Water Quality Certification

Under Section 401 of the Clean Water Act, the RWQCB has regulatory authority over actions in waters of the United States and/or the State of California through the issuance of water quality certifications, which are issued in conjunction with any federal permit (e.g., permits issued by the USACE under Section 404 of the Clean Water Act, described below). Section 401 of the Clean Water Act provides the SWRCB and the RWQCBs with the regulatory authority to waive, certify, or deny any proposed activity that could result in a discharge to surface waters of the State. To waive or certify an activity, these agencies must find that the proposed discharge would comply with State water quality standards, including those protecting beneficial uses and water quality. If these agencies deny the proposed activity, the federal permit cannot be issued. This water quality certification is generally required for projects involving the discharge of dredged or fill material to wetlands or other water bodies.

Federal Clean Water Act Section 404

Proposed discharges of dredged or fill material into waters of the United States require USACE authorization under Section 404 of the CWA (33 U.S.C. 1344). Waters of the United States generally include tidal waters, lakes, ponds, rivers, streams (including intermittent streams), and wetlands (with the exception of isolated wetlands).

The USACE identifies wetlands using a "multi-parameter approach," which requires positive wetland indicators in three distinct environmental categories: hydrology, soils, and vegetation. According to the *Corps of Engineers Federal Wetlands Delineation Manual*, except in certain situations, all three parameters must be satisfied for an area to be considered a jurisdictional wetland (Environmental Laboratory 1987). The *Interim Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Arid West Region* (USACE 2008) is also utilized when conducting jurisdictional wetland determinations in areas identified within the boundaries of the arid west. The study area falls within the Arid West Region (which includes most of the Central California Coast and inland) and, therefore, the assessment of wetlands used the Arid West guidance and the federal manual.

Section 303(d) List of Impaired Water Bodies and Total Maximum Daily Loads

In accordance with Section 303(d) of the Clean Water Act, state governments must present the U.S. EPA with a list of “impaired water bodies,” defined as those water bodies that do not meet water quality standards, even after point sources of pollution have been equipped with the minimum required levels of pollution control technology. Placement of a water body on the Section 303(d) List of Impaired Water Bodies acts as the trigger for developing a Total Maximum Daily Load (TMDL) pollution control plan for each water body and associated pollutant/stressor on the list. The TMDL is the quantity of a pollutant that can be safely assimilated by a water body without violating water quality standards. The TMDL serves as the means to attain and maintain water quality standards for the impaired water body to support designated and potential beneficial uses identified in the Basin Plan. During each Section 303(d) listing cycle, the water bodies on the list are prioritized and a schedule is established for completing the TMDLs. Table 5.16-1 (Impaired Surface Water Bodies) lists impaired water bodies in the Project area.

NPDES Waste Discharge Regulations

In 1987, amendments to the Clean Water Act added Section 402, which established a framework to protect water quality by regulating industrial, municipal, and construction-related sources of pollutant discharges to waters. In California, the National Pollutant Discharge Elimination System (NPDES) program is administered by the SWRCB through the RWQCBs and requires municipalities to obtain permits that outline programs and activities to control wastewater and stormwater pollution. The NPDES program provides two levels of control for the protection of water quality: technology-based limits and water-quality-based limits. Technology-based limits are based on the ability of dischargers to treat the water, while water-quality-based limits are required if technology-based limits are not sufficient to protect the water body. The water-quality-based effluent limitations required to meet water quality criteria in the receiving water are based on the National Toxics Rule, the California Toxics Rule, and the Basin Plan. NPDES permits must also incorporate TMDL waste load allocations when they are developed.

NPDES Construction General Permit (SWRCB Order No. 2009-09-DWQ)

The federal Clean Water Act prohibits discharges of stormwater from construction projects unless the discharge is in compliance with an NPDES permit. The SWRCB, the permitting authority in California, adopted an NPDES General Permit for Stormwater Discharges Associated with Construction and Land Disturbance Activities (Construction General Permit) (Order No. 2009-0009, as amended by Order No. 2010-0014; SWRCB 2010, 2011). Order No. 2009-0009 took effect on July 1, 2010 and was amended on February 14, 2011. The Order applies to construction sites that include one or more acre of soil disturbance. Construction activities include clearing, grading, grubbing, excavation, stockpiling, and reconstruction of existing facilities involving removal or replacement.

The Construction General Permit requires that the landowner and/or contractor file permit registration documents prior to commencing construction and then pay a fee annually through the duration of construction. These documents include a notice of intent, risk assessment, site map, stormwater pollution prevention plan (SWPPP), and signed certification statement. The permit specifies a risk-based permitting approach that includes requirements specific to three overall levels of risk, which are determined based on the potential for a project to cause sedimentation, as well as the sensitivity of the receiving water to sedimentation. The three risk levels are used to determine specific numeric action levels and effluent limitations for pH and turbidity, as well as requirements for a rain event action plan, best management practices (BMP) implementation, monitoring, and reporting.

The SWPPP must include measures to ensure that: all pollutants and their sources are controlled; non-stormwater discharges are identified and eliminated, controlled, or treated; site BMPs are effective and result in the reduction or elimination of pollutants in stormwater discharges and authorized non-stormwater discharges; and the BMPs installed to reduce or eliminate pollutants after construction are completed and maintained. The SWPPP must demonstrate that calculations and design details, as well as BMP controls for site runoff, are complete and correct. Non-stormwater discharges include those from improper dumping, accidental spills, and leakage from storage tanks or transfer areas. The Construction General Permit specifies minimum BMP requirements for stormwater control based on the risk level of the site. Post-construction stormwater runoff reduction requirements must be implemented at project sites not covered by a Phase I or Phase II municipal stormwater permit. The post-construction stormwater standards address water quality, runoff reduction, drainage density, and channel protection requirements for the receiving water. San Mateo County, including the Project area, is covered under a Phase I municipal stormwater permit. Thus, the Project would not be subject to the post-construction stormwater standards specified in the Construction General Permit.

The Construction General Permit stipulates that effluent and receiving water monitoring must demonstrate compliance with permit requirements and that project proponents must take corrective action if these limitations are exceeded. The results of the monitoring and corrective actions must be reported annually to the SWRCB. The Construction General Permit specifies minimum qualifications for a qualified SWPPP developer and qualified SWPPP practitioner (SWRCB 2010).

5.16.2.2 Local Regulations

San Mateo Countywide Water Pollution Prevention Program

The San Mateo Countywide Water Pollution Prevention Program (SMCWPPP) helps municipalities and unincorporated areas to comply with the countywide NPDES permit by ensuring that new development and redevelopment projects mitigate, to the maximum extent practicable, stormwater runoff impacts on water quality during both construction and operation of projects. As mentioned above, RWQCB Order No. R2-2009-0074 (Order) regulates discharges of stormwater water from municipalities in San Mateo County (RWQCB 2009b). Individual project sites creating more than 10,000 square feet of new impervious cover are subject to the "C.3" requirements established in Section C.3 of the Order and required to mitigate for water quality, including stormwater treatment measures to minimize stormwater pollutant discharges. In addition, development sites that create or replace one acre or more of impervious service may be subject to flow and volume reduction requirements. None of the GSR facility sites would create more than 10,000 square feet of new impervious cover and, therefore, are not subject to the C.3 requirements, nor to the flow and volume reduction requirements.

5.16.3 Impacts and Mitigations

5.16.3.1 Significance Criteria

For the purposes of this EIR, the Regional Groundwater Storage and Recovery Project would have a significant effect on hydrology and water quality if it were to:

Surface Water

- Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation on- or off-site.
- Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on- or off-site.
- Create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff.
- Place housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other authoritative flood hazard delineation map.
- Place within a 100-year flood hazard area structures that would impede or redirect flood flows.
- Expose people or structures to a significant risk of loss, injury, or death involving flooding, including flooding as a result of the failure of a levee or dam.
- Expose people or structures to a significant risk of loss, injury or death involving inundation by seiche, tsunami, or mudflow.
- Violate any water quality standards or waste discharge requirements.
- Otherwise substantially degrade water quality.

Groundwater

- Deplete groundwater supplies in a manner that would result in a lowering of the local groundwater to a level where the production rate of preexisting nearby wells would drop to a level that would not support existing or planned land uses.
- Lower groundwater levels in a manner that would result in onsite or offsite land subsidence that would cause substantial structural damage, increased flooding, or altered drainage patterns.
- Lower groundwater levels in a manner that would result in seawater intrusion such that loss of beneficial uses of groundwater would occur.
- Change groundwater levels in a manner that would affect beneficial uses of surface water bodies.
- Violate any water quality standards or waste discharge requirements.
- Otherwise substantially degrade water quality.
- Deplete groundwater supplies or interfere with groundwater recharge in a manner that would result in a substantial regional deficit in aquifer storage that would not support existing or planned land uses.

5.16.3.2 Approach to Analysis of Construction Impacts

This section describes the approach to analyzing impacts related to construction of the proposed Project on surface water and groundwater resources. As explained below, construction of the proposed Project would not result in impacts related to some of the above listed significance criteria. The following criteria are not discussed further in the impact analysis, below, for the following reasons:

Place housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other authoritative flood hazard delineation map. The proposed Project does not include the construction of new housing or structures for human occupancy. Therefore, the significance criterion related to the placement of housing within a 100-year flood hazard zone is not applicable to the proposed Project and is not discussed further.

Place within a 100-year flood hazard area structures that would impede or redirect flood flows. The majority of the Project facility sites are not located within a FEMA mapped 100-year flood hazard zone. Although portions of the construction area boundaries at Sites 9 and 13 are located within a FEMA mapped 100-year flood hazard zone (FEMA 2012), construction within designated 100-year flood zones would have no impact given the negligible potential for stockpiles of soil or construction materials to displace floodwaters, raise flood elevations, or create new flooding impacts. Therefore, this significance criterion is not applicable to Project construction activities and is only discussed below as it relates to potential long-term operational impacts.

Expose people or structures to a significant risk of loss, injury, or death involving flooding, including flooding as a result of the failure of a levee or dam. The proposed Project does not include the construction of structures within an area subject to inundation from failure of a levee or dam (ABAG 2012). Therefore, the significance criterion related to flooding as a result of the failure of a levee or dam is not applicable to the proposed Project and is not discussed further.

Expose people or structures to a significant risk of loss, injury, or death involving inundation by seiche, tsunami, or mudflow. The proposed Project would have no effect on the frequency or probability of seiches (i.e., earthquake-induced oscillating waves in an enclosed water body), because the Project would not create new enclosed water bodies or affect the frequency of earthquakes. Further, the proposed Project does not include the construction of habitable structures near any isolated bodies of water subject to inundation by seiche. The proposed Project does not include the construction of structures within an area subject to inundation from tsunami (Cal EMA 2009). No mudflows have been mapped at the facility sites (USGS 1997). Other types of slope instability issues are discussed in Section 5.15, Geology and Soils. Therefore, the significance criterion related to inundation by seiche, tsunami, or mudflow is not applicable to the proposed Project and is not discussed further.

Surface Water Hydrology

The approach to analysis of construction impacts describes the methodology used to identify and evaluate impacts from construction activities. Construction could impact surface water hydrology and water quality.

The surface water hydrology and water quality analysis evaluates the proposed Project's construction activities that may have the potential to degrade existing water quality and increase erosion, or cause flooding. The analysis evaluates potential impacts from well facilities and proposed pipelines including the proposed and alternate water connection pipelines. Regional documents and maps were reviewed to identify hydrology and water quality resources that could be directly or indirectly affected by construction, operation, or maintenance activities. The analysis focuses on how construction of the proposed Project would affect hydrology or water quality of regional and local surface waters.

5.16.3.3 Approach to Analysis of Operational Impacts

This section describes the approach to analyzing impacts related to operations of the proposed Project.

The analysis of impacts of groundwater pumping operations relies on predicted groundwater-level changes in the South Westside Groundwater Basin that were modeled with the Westside Basin Groundwater Model, Version 3.1, supplemented by a spreadsheet-based Lake-Level model to evaluate predicted changes in Lake Merced water levels, as described in Section 5.1, Overview, Section 5.1.6 (Groundwater Modeling Overview). The technical report describing the groundwater modeling analysis is included as Appendix G (Groundwater Technical Reports) (Kennedy/Jenks 2012a). The results of the two models were used together with other appropriate analytical techniques to assess the potential for groundwater pumping to result in well interference, subsidence, surface water quality, groundwater quality, and groundwater depletion effects. Each impact analysis below includes a more detailed approach to analysis relevant to the particular impact.

Groundwater-level Modeling

As described in Section 5.1 Overview, Section 5.6.1 (Groundwater Modeling Overview), the Westside Basin Groundwater-flow Model was developed by the City of Daly City, with assistance from the City of San Bruno, Cal Water, and the SFPUC (HydroFocus 2011). The Westside Basin Groundwater-flow Model was used to model existing conditions and Project impacts to groundwater levels over a 47-year modeling period with initial conditions beginning in 2009, the year that the Notice of Preparation of an Environmental Impact Report (NOP) was issued (the NOP is provided in Appendix A). Three scenarios were modeled including the modeled existing conditions, pumping under the proposed Project, and cumulative pumping, which includes the proposed Project and other reasonably foreseeable groundwater pumping and surface water projects in the groundwater basin. The model inputs and results prepared for this EIR are called the Westside Basin Groundwater Model (Kennedy/Jenks 2012a).

As shown on Table 5.1-2 (Model Input – Pumping Assumptions for Modeling Scenarios) of Section 5.1, Overview, the modeled existing conditions include existing groundwater pumping under a variety of rainfall and temperature conditions for the entire 47-year simulation period, based upon historic hydrology data modified to include a design drought[16]. For the Project, the Westside Basin Groundwater Model considers a Put, Take, Hold sequence to simulate in-lieu groundwater recharge during wet (i.e., above-average) and normal rainfall years and groundwater extraction during dry years.

The cumulative model scenario combines the existing pumping in the Westside Groundwater Basin and Project pumping with other reasonably foreseeable changes in pumping in the basin (described in Section 5.1.6), including pumping that would occur with implementation of the San Francisco Groundwater Supply (SFGW) Project and the Holy Cross Cemetery buildout. The Vista Grande Drainage Basin Improvement Project is also included in the cumulative model scenario. While this project does not propose groundwater pumping, it is included as a cumulative project in the modeling because it would involve additions of stormwater runoff to Lake Merced, which would increase Lake Merced water levels and associated groundwater levels in the Shallow Aquifer.

As discussed in Section 5.1.6, the Westside Basin Groundwater Model is best used for evaluating relative changes in groundwater levels and also uses an assumed set of hydrologic conditions over the 47-year simulation period for each model scenario. Although future hydrologic conditions cannot be expected to occur exactly as modeled, using a broad range of hydrologic conditions observed over the recent 47-year historical period allows a reasonable evaluation of changes in groundwater levels that would be expected to occur over the simulation period. The modeled existing conditions include groundwater level changes that are predicted to occur over the 47-year simulation period in response to the assumed hydrology without Project-related or cumulative pumping. Therefore, in the impact analyses, the Project-related effects under Project and cumulative conditions are compared to the modeled existing conditions to distinguish the effect of Project-related pumping from the effects that would occur based only on changes in hydrologic conditions. Additional information used to evaluate specific impacts is addressed in the approach to analysis provided for each specific impact below.

The Westside Basin Groundwater Model was also used to predict groundwater levels during the 47-year simulation period. To characterize basin-wide groundwater conditions, which is necessary for the analysis of cumulative impacts, graphs showing modeled groundwater levels from representative locations in the North and South Westside Groundwater Basins are included in Appendix G (Groundwater Technical Reports). The graphs present results for each water year during the 47-year simulation period, which extends from October of the previous year through September of the subsequent year.

---

[16] The SFPUC measures water supply reliability using an 8.5-year "design drought." A design drought is a planning and operations tool used by water agencies to define a reasonable worst-case drought scenario in order to establish design and operating parameters for the water system. The WSIP uses a design drought based on the hydrology of the six years of the worst historical drought (1987-1992) on record, plus the 2.5 years of the 1976-1977 drought, for a combined total of an 8.5-year design drought sequence.

The graphs show predicted groundwater levels for modeled existing conditions, the proposed Project, and cumulative conditions in the Shallow Aquifer (or shallow water-bearing zones) and the Primary Production Aquifer. Evaluation of the water-level trends predicted in these graphs provides an overview of how the Project would likely affect groundwater levels in the North and South Westside Groundwater Basins. These effects are detailed in the impact analyses under the relevant hydrology and water quality impacts discussed below.

Summary of Groundwater Modeling Results

As indicated in the graphs, under the modeled existing conditions, there would likely be a normal variation in groundwater levels in the Basin in response to changing hydrologic conditions.

In the South Westside Groundwater Basin, groundwater levels in both the shallow water-bearing zone and the Primary Production aquifer are predicted to be higher under the Project than under modeled existing conditions for 70 to 80 percent of the simulation. As shown in Figure 5.1-2 (Effects of Project and Cumulative Conditions relative to Modeled Existing Conditions on Groundwater Storage Volumes in the Westside Groundwater Basin), groundwater storage volumes in the Westside Groundwater Basin as a whole are also predicted to be higher under the Project for 70 to 80 percent of the 47-year simulation than under modeled existing conditions. Groundwater levels and groundwater storage volumes are predicted to be lower under the Project than under modeled existing conditions for approximately 20 to 30 percent of the simulation, especially during the design drought.

In the South Westside Groundwater Basin, predicted changes in groundwater levels and groundwater storage volumes under the cumulative conditions generally follow the same trend as the Project, except with slightly lower groundwater levels relative to modeled existing conditions in the Daly City area, as a result of pumping under the SFGW Project. The effect of cumulative pumping would be diminished farther to the south, due to the intervening distance, and no effect would be observed as far south as San Bruno.

Westlake Pump Station

Due to the nature of the proposed Project, there would be no operational impacts on hydrology or water quality related to Project operations at the Westlake Pump Station for the reasons described below:

Project operations at the Westlake Pump Station would have no impacts on groundwater. The Project at this location includes operation of new or upgraded pumps to convey water from the Project wells at Sites 2, 3, and 4 to the Daly City water distribution system and does not include pumping of groundwater. Upgrades to the Westlake Pump Station would include new chemical storage tanks, metering pumps, a resized transformer, and new booster pumps. The upgrades would not discharge waste to the groundwater or pump groundwater to the surface. As a result, there would be no impact from potential groundwater contamination at this site. In addition, no discharges to surface waters would occur from increased treatment volumes at the pump station site, as any discharges would go to the sanitary sewer. Operational impacts at the Westlake Pump Station are therefore not discussed further.

Groundwater-surface Water Interactions

Due to the location of the proposed Project and its distance from Golden Gate Park, there would be no impact related to the Groundwater-Surface Water Interactions significance criterion for the Golden Gate Park lakes; therefore, no impact discussion is provided for the reasons described below:

Golden Gate Park Lakes Surface Water Effects. Golden Gate Park is located at the northernmost extent of the Westside Basin. The average depths to groundwater indicate that these shallow lakes do not intersect the water table and thus groundwater-surface water interaction does not affect surface water conditions in the Golden Gate Park lakes. The operation of the GSR Project, including both Put and Take Years, is not anticipated to affect this area, because it is too far away from Project pumping and in-lieu recharge. For both reasons – the lack of groundwater-surface water interaction and distance – the Project would not affect water levels or water quality in the Golden Gate Park lakes. (Kennedy/Jenks 2012d)

Water Quality Standards

As described below there would be no operation-related water quality impacts relative to the following issues:

Violate waste discharge requirements. The proposed Project operation would not discharge any type of waste to groundwater; therefore, no waste discharge requirements would apply to the Project relative to groundwater.

Violate drinking water standards relative to specific constituents for which the SFPUC would provide treatment. As described in Chapter 3, Project Description, Section 3.4.2.2 (Well Facility Types), the SFPUC proposes to provide treatment as needed to meet State and federal drinking water standards for bacteria and micro-organisms, pH, iron, manganese, nitrate, VOCs, or other similar constituents. The SFPUC also proposes to provide fluoridation as required to meet Title 22 of the California Code of Regulations, as described in Chapter 3, Project Description, Section 3.4.2.2 (Well Facility Types). Project Description Table 3-3 (Site-specific Facility Characteristics), describes the proposed treatment of groundwater at each of the well sites. Treatment systems include disinfection to comply with the primary MCLs for bacteria and micro-organisms, pH adjustment, iron and/or manganese removal to comply with secondary MCLs regarding odor and taste, and fluoridation. At Sites 12 and 19 (Alternate), blending of Project groundwater with existing surface water supplies is proposed to comply with secondary MCLs for iron and/or manganese. The proposed treatment systems are capable of providing required levels of disinfection, pH adjustment, reduction in iron and manganese concentrations, and fluoridation so that State and federal drinking water standards would be met (MWH et al. 2008). Because the SFPUC's proposal, as described in Chapter 3, Section 3.4.2.2 (Well Facility Types), provides treatment as needed to meet State and federal drinking water standards for these constituents, no additional analysis of the potential to violate these drinking water standards is needed. Therefore, the significance criterion related to drinking water standards (for constituents for which treatment would be provided) is not applicable to operation of the Project and is not discussed further.

5.16.3.4 Summary of Impacts

For the significance criteria that have not already been deemed "not applicable" in the Approach to Analysis section above, the specific impact analyses below are divided into two subsections: (1) construction impacts (short-term) and (2) operational impacts (long-term). Table 5.16-6 (Summary of Surface Water Hydrology and Water Quality Construction and Operational Impacts) provides a summary of potential impacts from construction and operation of the Project, including cumulative construction impacts that would occur on a site-specific basis. Table 5.16-7 (Summary of Hydrology and Water Quality Operational and Cumulative Impacts relative to Proposed Project Pumping and In-Lieu Recharge) provides a summary of potential impacts from operation of the Project, including cumulative impacts, which would occur due to overall Project pumping and in-lieu recharge. There would be no operational impacts at the Westlake Pump Station; therefore the Westlake Pump Station is not included in the operational impacts summary table.

TABLE 5.16-7
Summary of Hydrology and Water Quality Operational and Cumulative Impacts relative to Proposed Project Pumping and In-lieu Recharge

Impact	Significance Level
Project Operational Impacts	
Impact HY-6: Project operation would decrease the production rate of existing nearby irrigation wells due to localized groundwater drawdown within the Westside Groundwater Basin such that existing or planned land use(s) may not be fully supported.	SUM[(a)]
Impact HY-7: Project operation would not result in substantial land subsidence due to decreased groundwater levels in the Westside Groundwater Basin where the historical low water levels are exceeded.	LS
Impact HY-8: Project operation would not result in seawater intrusion due to decreased groundwater levels in the Westside Groundwater Basin.	LS
Impact HY-9: Project operation could have a substantial, adverse effect on water quality that could affect the beneficial uses of Lake Merced.	LSM
Impact HY-10: Project operation would not have a substantial adverse effect on water quality that could affect the beneficial uses of Pine Lake.	LS
Impact HY-11: Project operation would not have a substantial adverse effect on water quality that could affect the beneficial uses of Colma Creek, San Bruno Creek, Lomita Channel, or Millbrae Creek.	LS
Impact HY-12: Project operation would not cause a violation of water quality standards due to mobilization of contaminants in groundwater from changing groundwater levels in the Westside Groundwater Basin.	LS
Impact HY-13: Project operation would not result in degradation of drinking water quality or groundwater quality relative to constituents for which standards do not exist.	LS
Impact HY-14: Project operation may have a substantial adverse effect on groundwater depletion in the Westside Groundwater Basin over the very long term.	LSM
Operational Cumulative Impacts	
Impact C-HY-2: Operation of the proposed Project would result in a cumulatively considerable contribution to cumulative impacts related to well interference.	SUM[(a)]
Impact C-HY-3: Operation of the proposed Project would not result in a cumulatively considerable contribution to cumulative impacts related to subsidence.	LS
Impact C-HY-4: Operation of the proposed Project would not have a cumulatively considerable contribution to seawater intrusion.	LS
Impact C-HY-5: Operation of the proposed Project could have a cumulatively considerable contribution to cumulative impacts on beneficial uses of surface waters.	LSM
Impact C-HY-6: Operation of the proposed Project would not result in a cumulatively considerable contribution to cumulative impacts related to water quality standards.	LS
Impact C-HY-7: Operation of the proposed Project would not result in a cumulatively considerable contribution to cumulative impacts related to water quality degradation.	LS
Impact C-HY-8: Operation of the proposed Project would have a cumulatively considerable contribution to a cumulative impact related to groundwater depletion effect.	LSM

Notes:

(a) Implementation of Mitigation Measure M-HY-6 (Ensure Existing Irrigators' Wells Are Not Prevented from Supporting Existing or Planned Land Use Due to Project Operation) depends in part upon the willingness of the well owner to participate in the monitoring program. Therefore, while Mitigation Measure M-HY-6 could reduce the impacts of well interference to a *less-than-significant* level, its implementation cannot be assured at this time. As a result, Impact HY-6 is conservatively categorized as *significant and unavoidable with mitigation*.

LS = Less than Significant Impact, LSM = Less than Significant with Mitigation, SUM=Significant and Unavoidable Impacts

5.16.3.5 Construction Impacts and Mitigation Measures

Impact HY-1: Project construction activities would degrade water quality as a result of erosion or siltation caused by earthmoving activities or by the accidental release of hazardous construction chemicals during construction. (Less than Significant with Mitigation)

Discussion of Water Quality Degradation

The proposed Project could degrade water quality as a result of erosion caused by earthmoving activities during construction or the accidental release of hazardous construction chemicals. In general, water quality impacts would be substantial if a water quality standard were to be exceeded or a beneficial use were to be impacted due to changes in water quality caused by erosion and/or siltation or release of hazardous construction chemicals resulting from Project earthmoving activities.

Approach to Analysis

The surface water hydrology analysis evaluates the proposed Project's construction that may have the potential to increase erosion and/or siltation or otherwise degrade existing water quality. The analysis evaluates potential impacts from the construction of well facilities and proposed pipelines, including the proposed and alternate water connection pipelines.

Impact Discussion and Significance Determination

<u>All Sites</u>

Earthmoving activities associated with Project construction at well facility sites would temporarily alter existing drainage patterns at well facility sites, including vegetation removal, grading, excavation, and soil stockpiling. New pipelines would be installed using open-trench construction methods. Exposed soil from stockpiles, excavated areas, and other areas where ground cover would be removed could be transported elsewhere by wind or water. If not properly managed, this could increase sediment loads in receiving water bodies, thereby adversely affecting water quality and designated beneficial uses. Earthmoving activities could, therefore, have a *significant* impact on water quality.

Site excavation and grading would be minor, with grading to a maximum depth of five feet for building foundations and underlying utilities (see Chapter 3, Project Description, Section 3.5.1.2 [Construction of Well Facilities]). Pipelines to connect the new wells to the water, storm drain, and sanitary sewer systems would generally be excavated to a depth of up to six feet. The discharge of sediment-laden groundwater to the storm drain system during excavation dewatering could degrade water quality and violate water quality standards. Construction water discharges from excavation dewatering could, therefore, have a *significant* impact on water quality. Construction activities at all sites could also result in the accidental release of hazardous construction chemicals, such as adhesives, solvents, and fuels. If not managed appropriately, these chemicals could adhere to soil particles, become mobilized by rain or runoff, or infiltrate into groundwater, degrading water quality. Earthmoving activities and use of construction chemicals at all facility sites could, therefore, have a *significant* impact on water quality.

Mitigation Measure M-HY-1 (Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan) would reduce potential water quality impacts during Project construction activities to a *less-than-significant* level by requiring measures to control erosion and sedimentation of receiving water bodies and minimize the risk of hazardous materials releases to surface water bodies. At sites where more than one acre of land would be disturbed, compliance with the requirements of the NPDES General Permit for Storm Water Discharges Associated with Construction Activity would be required. As a result, the potential impact on water quality would be *less than significant with mitigation*.

Mitigation Measure M-HY-1: Develop and Implement a Storm Water Pollution Prevention Plan (SWPPP) or an Erosion and Sediment Control Plan (All Sites)

Consistent with the requirements of the NPDES General Permit for Storm Water Discharges Associated with Construction Activity, at sites where more than one acre of land disturbance would occur (Sites 3, 4, 5, 6, 7, 12, 13, and 14), the SFPUC or its contractor(s) shall develop a Storm Water Pollution Prevention Plan (SWPPP), submit a notice of intent to the SWRCB's Division of Water Quality and implement site-specific BMPs to prevent discharges of nonpoint-source pollutants in construction-related stormwater runoff into downstream water bodies.

At sites where less than one acre of land disturbance would occur (Sites 1, 2, 8, 9, 10, 11, 15, 16, 17 Alternate, 18 Alternate, 19 Alternate, and the Westlake Pump Station), the SFPUC or its contractor(s) shall prepare and implement Erosion and Sediment Control Plans (ESCPs).

The SWPPPs and ESCPs shall include sufficient measures to address the overall construction of the Project and, at a minimum, construction contractors should all undertake the following measures, as applicable, to minimize any adverse effects on water quality:

Scheduling

- Schedule construction to minimize ground disturbance during the rainy season.
- Stabilize all disturbed soils as soon as possible following the completion of soil disturbing work in the Project area.
- Stabilize soil with vegetation or physical means in the event rainfall is expected.
- Install erosion and sediment control BMPs prior to the start of any ground-disturbing activities.

Erosion and Sedimentation

- Preserve existing vegetation in areas where no construction activity is planned or where construction activity will occur at a later date.
- Stabilize and revegetate disturbed areas as soon as possible after construction by planting or seeding and/or using mulch (e.g., straw or hay, erosion control blankets, hydromulch, or other similar material).
- Install silt fences or fiber rolls or implement other suitable measures around the perimeters of the construction zone, staging areas, temporary stockpiles, spoil areas, stream channels, and swales, as well as down-slope of all exposed soil areas and in other locations determined necessary to prevent offsite sedimentation.

- Install temporary slope breakers during the rainy season on slopes greater than five percent where the base of the slope is less than 50 feet from a water body, wetland, or road crossing at spacing intervals required by the SWRCB Construction General Permit.
- Use filter fabric or other appropriate measures to prevent sediment from entering storm drain inlets.
- Detain and treat water produced by the dewatering of construction sites using sedimentation basins, sediment traps (when water is flowing and there is sediment), or other measures to ensure that discharges to receiving waters meet applicable water quality objectives.

Tracking Controls

- Grade and stabilize construction site entrances and exits to prevent runoff from the site and to prevent erosion.
- Remove any soil or sediment tracked off paved roads during construction by employing street sweeping.

Non-stormwater Control

- Keep construction vehicles and equipment clean; do not allow excessive buildup of oil and grease.
- Check construction vehicles and equipment daily at startup for leaks and repair any leaks immediately.
- Do not refuel vehicles and equipment within 50 feet of surface waters to prevent run-on and runoff and to contain spills.
- Conduct all refueling and servicing of equipment with absorbent material or drip pans underneath to contain spilled fuel. Collect any fluid drained from machinery during servicing in leak-proof containers and deliver to an appropriate disposal or recycling facility.
- Contain fueling areas to prevent run-on and runoff and to contain spills.
- Cover all storm drain inlets when paving or applying seals or similar materials to prevent the offsite discharge of these materials.

Waste Management and Hazardous Materials Pollution Control

- Remove trash and construction debris from the Project area regularly. Provide an adequate number of waste containers with lids or covers to keep rain out of the containers and to prevent trash and debris from being blown away during high winds.
- Locate portable sanitary facilities a minimum of 50 feet from creeks or waterways.
- Ensure the containment of sanitation facilities (e.g., portable toilets) to prevent discharges of pollutants to the stormwater drainage system or receiving water.

- Maintain sanitary facilities regularly.
- Store all hazardous materials in an area protected from rainfall and stormwater run-on and prevent the offsite discharge of leaks or spills.
- Inspect dumpsters and other waste and debris containers regularly for leaks and remove and properly dispose of any hazardous materials and liquid wastes placed in these containers.
- Train construction personnel in proper material delivery, handling, storage, cleanup, and disposal procedures.

BMP Inspection, Maintenance and Repair

- Inspect all BMPs on a regular basis to confirm proper installation and function.
- Inspect all stormwater BMPs daily during storms.
- Inspect sediment basins, sediment traps and other detention and treatment facilities regularly throughout the construction period.
- Provide sufficient devices and materials (e.g., silt fence, fiber rolls, erosion blankets, etc.) throughout Project construction to enable immediate repair or replacement of failed BMPs.
- Inspect all seeded areas regularly for failures and remediate or repair as soon as feasible.

Permitting, Monitoring, and Reporting

- Provide the required documentation for inspections, maintenance and repair requirements.
- Monitor water quality to assess the effectiveness of control measures.
- Maintain written records of inspections, spills, BMP-related maintenance activities, corrective actions and visual observations of any offsite discharge of sediment or other pollutants.
- Notify the RWQCB and other agencies as required (e.g., California Department of Fish and Wildlife) if the criteria for turbidity, oil/grease, or foam are exceeded and undertake corrective actions.
- Immediately notify the RWQCB and other agencies as required (e.g., California Department of Fish and Wildlife) of any spill of petroleum products or other organic or earthen materials and undertake corrective action.

Post-construction BMPs

- Revegetate all temporarily disturbed areas as required after construction activities are completed.
- Remove any remaining construction debris and trash from the Project area and staging areas upon Project completion.

- Phase the removal of temporary BMPs as necessary to ensure stabilization of the site.
- At sites covered under the NPDES General Construction Permit, correct post-construction site conditions, as necessary, to comply with the SWPPP and any other pertinent RWQCB requirements.

Impact Conclusion: Less than Significant with Mitigation

Impact HY-2: Discharge of groundwater could result in minor localized flooding, violate water quality standards, and/or otherwise degrade water quality. (Less than Significant with Mitigation)

Discussion of Water Quality Degradation

The proposed Project could cause minor localized flooding and degrade water quality as a result of groundwater discharges associated with well construction as discussed below. In general, water quality impacts would be substantial if a water quality standard were to be exceeded or a beneficial use were to be impacted due to changes in water quality caused by discharge activities.

Approach to Analysis

The analysis evaluates potential impacts from groundwater discharge during well development and testing activities. The amount and location of groundwater discharge were evaluated to determine potential impacts on water quality and flooding for each well facility site. Regional documents and maps were reviewed to identify hydrology and water quality resources that could be directly or indirectly affected by construction activities. The analysis focuses on how discharge of groundwater would affect hydrology or water quality of regional and local surface waters.

Impact Discussion and Significance Determination

The evaluation of impacts that follows discusses sites with no impacts first, followed by sites with significant impacts.

<u>Westlake Pump Station</u>

Upgrades at the Westlake Pump Station would be located within the existing pump station building and would not generate groundwater that would need to be discharged to a local storm drain or sanitary sewer system. Therefore, there would be *no impact* on flooding or water quality resulting from groundwater discharges at the Westlake Pump Station.

Impact Conclusion: No Impact

<u>Sites 1 through 19 (Alternate)</u>

Sites 1, 3, 4, 7, 9, 11, 12, 14, 15, 16, 17(Alternate), 18 (Alternate), and 19 (Alternate)

Following drilling of the production wells at these sites, the wells would be developed and various well pumping tests would be performed. Final development of the well would be performed by surging and pumping using a temporary test pump. Well pumping tests would include pumping for durations of two hours each at different discharge rates, as well as continuous pumping for 12 to 48 hours at the final design capacity of the well. Up to three million gallons of groundwater would be produced from a well during the final well development and pumping tests, which would be discharged to the local storm drain and/or the sanitary sewer. The peak discharge rate during well development (lasting for a few hours) would be approximately 800 gallons per minute (gpm); the typical discharge rate would be closer to 500 gpm. The development and testing would occur over the course of approximately 150 hours for each well resulting in an average discharge of 0.5 million gallons per day (see Chapter 3, Project Description, Section 3.5.1.1 [Construction Methods for Production Wells]).

The discharge of sediment-laden groundwater to the storm drain system during well development and pumping tests could degrade water quality and violate water quality standards. Depending on the rate of discharge, the discharged effluent could also cause minor localized flooding if discharge rates exceeded the capacity of local storm drains. Discharges of groundwater from well development and pump tests at these sites could, therefore, have a *significant* impact on water quality.

Before being placed into service, the chemical and filtration facilities and new pipelines would be flushed and disinfected to meet water quality regulations (see Chapter 3, Project Description, Section 3.5.1.4 [Dewatering and Other Potential Discharges]). All water used for flushing would come from the new wells and would be discharged to the nearest sanitary sewer and conveyed to local wastewater treatment plants for processing. Therefore, there would be *no impact* on surface water quality related to disinfection of new chemical and filtration facilities and pipelines.

Mitigation Measure M-HY-2 (Management of Well Development and Pump Testing Discharges) would reduce potential water quality impacts from well development and pump testing to a *less-than-significant* level by requiring the construction contractor to prepare and implement a Project-specific discharge plan that specifies how effluent would be managed to protect water quality.

Mitigation Measure M-HY-2: Management of Well Development and Pump Testing Discharges (All Sites, Except Westlake Pump Station)

To address potential impacts on receiving water quality that could result during the construction period related to well development and pump testing, the SFPUC and its contractor shall: 1) prepare and implement a site-specific discharge plan; and 2) fully comply with NPDES requirements.

The discharge plan shall specify how the water will be collected, contained, treated, monitored, and discharged to the vicinity storm drainage system or sanitary sewer system. Discharges to storm drains are subject to review and approval by the RWQCB. The discharge plan shall at a minimum:

- Identify methods and locations for collecting and handling water on site prior to discharge, determine treatment requirements, and determine the capacity of holding tanks.
- Identify methods for treating water on site prior to discharge, such as filtration, coagulation, sedimentation settlement areas, oil skimmers, pH adjustment, and other BMPs.

- Establish procedures and methods for maintaining and monitoring discharge operations to ensure that no breach in the process occurs that could result in a failure to achieve/maintain the applicable water quality objectives of receiving waters.
- Identify discharge locations and include details regarding how the discharge will be conducted to minimize erosion and scour.

The proposed discharge is anticipated to be conditionally covered under San Mateo County's municipal stormwater permit (Order No. 99-059, NPDES Permit No. CAS002992), contingent upon compliance with certain conditions (RWQCB 2009b, 2012). Prior to any discharge to a storm drainage system, the SFPUC and its contractor shall request a determination from the RWQCB as to the type of permit under which the Project effluent discharges will be regulated. Based on that determination, the SFPUC shall prepare and submit all required and relevant Project information so that the RWQCB can issue appropriate guidelines and requirements (e.g., numerical effluent limitations, monitoring and reporting requirements). Based on previous discussions with the RWQCB (RWQCB 2009a, 2012), anticipated conditions include, but would not be limited to:

- The SFPUC shall notify affected stormwater agencies of the volume, rate, and location of the planned discharge at least 14 days before discharging.
- The discharged water shall not exceed 50 NTU. Turbidity shall be monitored every 15 minutes during the first hour of operation of any sedimentation or filtration device used to meet discharge limitations and once every two hours thereafter. If turbidity limits are exceeded for more than two hours, the discharge shall be terminated until turbidity limits can be complied with.
- The pH of the discharged water shall be within the range of 6.5 and 8.5 and pH shall be measured once per day during the discharge.
- The discharged water shall not cause pollution, contamination, or nuisance.
- The discharged water shall not cause scouring or erosion at the point of discharge of downstream from the discharge.
- Self-Monitoring Reports shall be submitted no later than 30 days following the last day of each month in which the discharges occur. These reports shall summarize turbidity measurements and approximate volumes of the discharges.

The construction contractor(s) shall comply with all monitoring and reporting requirements established by the RWQCB for discharges to storm drainage system. Any failure to achieve/maintain established narrative or numeric water quality objectives shall be reported to the RWQCB and corrective action taken. Corrective action may include an increase in residence time in treatment features (e.g., longer holding time in settling tanks) and/or incorporation of additional treatment measures, which could include but are not limited to the addition of sand filtration prior to discharge.

Sites 2, 5, 6, 8, 10, and 13

Test wells at Sites 2, 5, 6, 8, 10, and 13 have been installed and, therefore, would not further generate groundwater associated with initial well drilling and pumping test activities that would need to be discharged to a local storm drain or sanitary sewer system. Therefore, there would be *no impact* on surface water quality related to discharges from well drilling and pumping test activities.

As summarized for the other well sites above, before being placed into service, the chemical and filtration facilities and new pipelines at these sites would be flushed and disinfected to meet water quality regulations. All water used for flushing would come from the new wells and would be discharged to the nearest sanitary sewer and conveyed to local wastewater treatment plants for treatment. Therefore, there would be *no impact* on surface water quality related to the disinfection of new chemical and filtration facilities and pipelines.

Mitigation Measure M-HY-2 (Management of Well Development and Pump Testing Discharges) would reduce water quality impacts from dewatering discharges at these sites to a *less-than-significant* level by requiring by requiring the construction contractor to prepare and implement a Project-specific discharge plan that specifies how effluent would be managed to protect water quality.

> ***Mitigation Measure M-HY-2: Management of Well Development and Pump Testing Discharges (All Sites, Except Westlake Pump Station)***
> (See above for a description)

Impact Conclusion: Less than Significant with Mitigation

5.16.3.6 Operational Impacts and Mitigation Measures – Surface Water

Impact HY-3: Project operation would not alter drainage patterns in such a manner that could result in degraded water quality or cause on- or off-site flooding. (Less than Significant)

Description of Flooding Impacts

Operational impacts that have the potential to increase runoff that results in water quality impacts or on- or off-site flooding impacts would be significant.

Approach to Analysis

The amount of new impervious coverage at each site was evaluated to determine if it would increase runoff and impact water quality or cause on- or off-site flooding.

Impact Discussion and Significance Determination

The evaluation of impacts that follows discusses sites with no impacts first, followed by sites with less-than-significant impacts.

Westlake Pump Station

Upgrades at the Westlake Pump Station would be located within the existing pump station building and would not alter drainage patterns or add new impervious surfaces. Therefore, there would be *no impact* to water quality at the Westlake Pump Station related to alteration of drainage patterns.

Impact Conclusion: No Impact

Sites 1 through 19 (Alternate)

Project pipelines would be constructed below ground and would not increase the rate or amount of surface water runoff. The amount of proposed new impervious surfaces at the well facility sites ranges from a minimum of 205 square feet to a maximum of 3,675 square feet at individual sites (see Chapter 3, Project Description, Section 3.4.3 [Facility Sites]). The buildings and paved parking areas at all sites would result in limited amounts of new impervious surfaces. Therefore, project-related increases in stormwater runoff resulting from increases in impervious surfaces would not increase the potential for on- or off-site flooding and the impact would be *less than significant*.

Impact Conclusion: Less than Significant

Impact HY-4: Project operations would not impede or redirect flood flows. (Less than Significant)

Description of Flooding Impacts

Project facilities located within the 100-year flood hazard area could impede and redirect flood flows around the site resulting in inundation or flooding of the surrounding areas. If a Project facility were to be constructed in the 100-year flood hazard area and it were to redirect flood flows to a previously unaffected area, then the impact could be significant.

Approach to Analysis

As described in Section 5.16.1.2 (Regional Surface Water Hydrology) under the sub-heading "Flood, Seiche, and Tsunami," a portion of the construction areas for Sites 9 and 13 would be located in areas of a mapped 100-year flood zones. Locations, elevations, and sizes of the proposed facilities were evaluated to determine whether there would be a potential to redirect flood flows that could then impact previously unaffected areas with flooding.

Impact Discussion and Significance Determination

The evaluation of impacts that follows discusses sites with no impacts first, followed by sites with less-than-significant impacts.

Sites 1, 2, 3, 4, 5, 6, 7, 8, 10, 11, 12, 13, 14, 15, 16, 17 (Alternate), 18 (Alternate), 19 (Alternate), and the Westlake Pump Station

Permanent Project facilities at these sites would not be located within a FEMA mapped 100-year flood hazard zone. While portions of the construction work areas at Site 13 would be situated within 100-year flood hazard zones, there would be no permanent aboveground structures remaining in the flood zone at this site. Therefore, there would be *no impact* at these sites related to the potential for impeding or redirecting flood flows.

Impact Conclusion: No Impact

Site 9

Site 9 would be located approximately 25 feet from channelized sections of the Colma Creek Diversion Channel and the San Mateo County Flood Control Channel. According to the current FEMA Flood Insurance Rate Mapping for the area near Site 9, a portion of the proposed chemical treatment building and parking lot would be within the mapped 100-year flood hazard zone along the San Mateo County Flood Control Channel (FEMA 2012). The placement of fill and construction of aboveground facilities within a flood hazard zone have the potential to impede or redirect flood flows. Aboveground facilities that are not designed to withstand inundation can be damaged during flood events. Underground facilities, such as pipelines, would not affect flood flows.

The potential for the site facilities to displace floodwaters, raise flood elevations, create new flooding impacts (e.g., by causing flooding of existing facilities or structures that previously would not have been inundated), or exacerbate existing flooding problems would be *less than significant*, given that the chemical treatment building at Site 9 would be elevated above the 100-year flood elevation (Chapter 3, Project Description, Section 3.4.3 [Facility Sites]). Also, the presence of the at-grade parking area would have a negligible effect on impeding or redirecting flood flows and would therefore not adversely affect surrounding areas.

Impact Conclusion: Less than Significant

Impact HY-5: Project operations would not result in a violation of water quality standards or in the degradation of water quality from the discharge of groundwater during well maintenance. (Less than Significant)

Description of Water Quality Impacts

Water quality impacts could occur from groundwater discharge during well maintenance activities such that water quality standards are exceeded or a beneficial use is adversely affected. If groundwater discharges were to contribute to runoff that could exceed the capacity of an existing storm drain system or if runoff from maintenance activities were to alter existing drainage patterns of the site or area and thereby cause substantial erosion or siltation, then such impacts could be significant.

Approach to Analysis

The proposed groundwater discharge volumes and durations were evaluated to determine whether the existing storm drain and sanitary sewer systems could accommodate the anticipated flow rates.

Impact Discussion and Significance Determination

The evaluation of impacts that follows discusses sites with no impacts first, followed by sites with less-than-significant impacts.

Westlake Pump Station

Upgrades at the Westlake Pump Station would be located within the existing pump station building and would not generate groundwater that would need to be discharged to a local storm drain or sanitary sewer system. Therefore, there would be *no impact* on water quality at the Westlake Pump Station related to groundwater discharges during Project operation.

Impact Conclusion: No Impact

Sites 1 through 19 (Alternate)

Weekly or monthly exercising of the production wells for one to four-hour periods would be required to ensure that the facilities remain operational. The wells at Sites 2, 3, 4, 5 (Consolidated at Site 6), 7 (Consolidated at Site 6), 14, and 19 (Alternate) would be connected to the storm drain system for disposing of pumped water that would be generated during well exercising. Chemical treatment and filtration would not be needed at these sites; therefore, these wells would not generate chloraminated water or filter backwash.

Underground piping would connect well facilities at Sites 1, 5 (On-site Treatment), 6, 7 (On-site Treatment), 8, 9, 10, 11, 12, 13, 15, 16, 17 (Alternate), and 18 (Alternate) to the local storm drain system and/or the sanitary sewer system to allow the discharge of groundwater during well exercising, including chloraminated water or filter backwash. Chloraminated water would be dechlorinated and sent to the storm drain or, if not treated, sent to the local sanitary sewer system, as described in Chapter 3, Project Description, Section 3.8.3, Maintenance. The determination of where to send the chloraminated water would be based on operational constraints such as the duration and volume of the discharge and the distance to the closest sanitary sewer. Backwash from the iron/manganese removal facilities would be sent to the local sanitary sewer system.

As discussed in the Section 5.12, Utilities and Service Systems, Section 5.12.1.1 (Utilities) and under Impacts UT-2 and UT-5, the existing sanitary sewer and storm drain systems have adequate capacity to accommodate the discharge volumes from the proposed well exercising. All discharge water would be sent to either the sanitary sewer or the storm drain system; therefore, the discharge water associated with operations of the Project would not violate water quality standards or degrade water quality and any such potential impacts would be *less than significant*.

Impact Conclusion: Less than Significant

5.16.3.7 Operation Impacts and Mitigation Measures – Groundwater

Impact HY-6: Project operation would decrease the production rate of existing nearby irrigation wells due to localized groundwater drawdown within the Westside Groundwater Basin such that existing or planned land use(s) may not be fully supported. (Significant and Unavoidable with Mitigation)

Description of Estimated Project Effects on Existing Irrigation Wells

Existing irrigation wells are wells owned and operated by parties other than the Project Partner Agencies. The existing irrigation wells identified in the South Westside Groundwater Basin are wells used to irrigate cemeteries and golf clubs, as shown in Figure 5.16-6 (Existing Irrigation Wells in the South Westside Groundwater Basin). During most Put and Hold Years, the Project would increase groundwater levels relative to modeled existing conditions, and existing irrigation wells would benefit from the higher water levels, by experiencing increased production rates. Higher water levels are expected during about 70 to 80 percent of the modeled time period (Kennedy/Jenks 2012b). During Take Years (dry years), pumping at Project wells would take place and could cause groundwater levels to decline below levels that are predicted under modeled existing conditions (i.e., levels predicted to occur without operation of the Project under existing conditions considering the historic range of hydrologic and rainfall conditions). If the Project were to decrease groundwater levels in the Westside Groundwater Basin near existing irrigation wells, adverse effects from well interference could result. If well interference were great enough, irrigation water currently supplied by existing irrigation wells could be decreased to the extent that existing irrigation uses, such as for turf at cemeteries and at golf clubs, would not be fully supported. The quality of turf grass at cemeteries and golf clubs is an important component of the attractiveness of these facilities and hence for the economic viability of these land uses. Insufficient irrigation water would result in a deterioration of existing turf grass and landscaping, affecting operating conditions at both golf clubs and cemeteries.

Pumping at a well causes groundwater levels to decline in the area around the well. The area of groundwater level decline is known as the cone of depression. Well interference occurs when a well's cone of depression comes into contact with or overlaps the cone of depression from another well (see Figure 5.16-7 [Well Interference Schematic]) (Driscoll 1986).

Well Interference from Overlapping Cones of Depression

Composite cone results in a lower pumping water level in each well, compared to individual cone of depression pumping water level.

Well Interference Schematic

Regional Groundwater Storage and Recovery Project

Figure 5.16-7

In the Westside Groundwater Basin, well interference (i.e., lower groundwater levels at an affected well) can affect operation of a well in several ways:

- Lower groundwater levels increases the distance the water has to travel vertically to reach the ground surface (this distance is known as the pumping lift). Greater pumping lift results in a decrease in the pump's discharge rate, which is the rate that water is delivered from the aquifer to the surface by the pump.
- If groundwater levels drop below the top of the well screen[17], less of the well screen provides water, which may result in a decrease in the pump's discharge rate.
- If groundwater levels drop below the top of the well screen, there is an increased risk of damage to the well from corrosion of the screen and/or to the pump from aeration of the well water. While such damage may not occur immediately or decrease the pump's discharge rate immediately, it may decrease the discharge rate over time.

The reduction in a pump's discharge rate or an increase in risk of damage to a pump or well does not necessarily prevent a well from meeting the demand for water needed to support a particular land use, because overall demand can sometimes be met with longer durations of pumping at a reduced rate.

To understand the potential for well interference impacts from the Project, this section describes existing wells that may experience well interference, including the depth and pump discharge rate of each well.

Existing Irrigation Wells and Associated Land Uses

Proposed Project wells would be located in areas near existing wells where well interference would potentially occur. These existing irrigation wells are not owned by the Project proponent (the SFPUC) or the Partner Agencies, but instead are owned by private land owners. Significant well interference is not expected to occur beyond 1.5 miles from a Project well and, therefore, the study area for well interference is limited to areas within 1.5 miles of a Project well[18]. The limitation of 1.5 miles was selected to represent a reasonable extent for a cone of depression given consideration of vertical leakage from one aquifer to another, groundwater recharge, interception of groundwater flow that otherwise discharges from the aquifer, and/or encountering a surface water body. (Fugro 2012a)

The primary land uses supported by groundwater in the South Westside Groundwater Basin – and within the study area – are cemeteries and golf clubs, which use groundwater to irrigate turf. Three of these golf clubs use mostly recycled water to irrigate their golf courses, but also use some groundwater

---

[17] The well screen is a perforated section of the well casing which allows groundwater from the aquifer to be pumped into the well casing and then to the ground surface.

[18]The Green Hills Golf Club wells are approximately 0.75 mile from the southernmost proposed Project well at Site 16. The Green Hills Golf Club wells are screened in the Shallow Aquifer under unconfined conditions. The Green Hills Golf Club wells would not be affected by pumping from the Project due to the smaller proposed pumping capacity at Site 16 (which is the only Project well that would be within 1.5 miles) and because of differences in well screen depths and geologic conditions between the Green Hills Golf Club wells and the proposed Project well at Site 16 (Fugro 2012a).

(LSCE 2010). The other cemeteries and golf clubs are reliant upon groundwater or surface water as their source of irrigation water supply.

The SFPUC invited cemetery and golf club owners and representatives to a Project workshop held on June 25, 2009 at the Colma Town Hall. Plans for the Project were presented and attendees were informed that the SFPUC was conducting a survey of existing irrigators' well owners as part of a series of studies in the Westside Groundwater Basin. A data request list pertaining to the well survey was made available to all attendees. (Fugro 2012a)

As a follow-up to the workshop, the SFPUC conducted site visits and/or meetings at the cemeteries and golf clubs. If permitted by the site owner or representative, site visits included well visits where Global Positioning System (GPS) coordinates were obtained and water levels measured if the well had an access port. Well visits occurred at all the cemeteries and golf clubs listed in Table 5.16-8 (Existing Irrigators' Wells Identified as a Primary, Active, or Secondary Well that May Be Affected by the Project) (well visits to the San Francisco Golf Club and Olympic Club occurred prior to 2009). (Fugro 2012a)

Table 5.16-8 lists the cemetery and golf club irrigation wells in the South Westside Groundwater Basin that may be affected by well interference from the Project. The table includes wells identified as primary, active, or secondary wells. Backup wells are not included, because they do not support land use on a regular basis. Based on a review of California Department of Water Resources (DWR) well completion reports and information from well owners (Fugro 2012a), the cemetery and golf club wells are generally found to be screened in the Primary Production Aquifer (see Figure 5.16-6 [Existing Irrigation Wells in the South Westside Groundwater Basin]). Some of the cemetery and golf club wells have screen intervals that extend into the Deep Aquifer.

Table 5.16-8 also lists the top of screen of the wells. The screen of a well is open to groundwater inflow from the aquifer. The rated capacity of the pump installed in each well for which the information is available is also provided in Table 5.16-8 (Fugro 2012a). The rated capacity of the pump is the discharge rate established by the manufacturer applied to specified conditions.

Estimated Peak Irrigation Demand for Land Uses Supported by Existing Irrigators' Wells

The existing wells where interference may occur due to the Project are irrigation wells that pump groundwater to maintain turf at either cemeteries or golf clubs. In most cases, the SFPUC does not have data showing the actual volume of irrigation water used at the cemeteries and some golf clubs[19]. Therefore, demand for irrigation water at these facilities was estimated in order to determine if the water

[19] The volume of irrigation water used at cemeteries and golf clubs is not available in most cases, because the irrigation users do not meter their existing wells. In some cases, data regarding the volume of irrigation water may exist, but the irrigation user declined to provide such data to the SFPUC upon request. For detailed information about meetings with irrigation users, see *South Westside Basin Third Party Well Survey and Well Interference Analysis* (Fugro 2012a).

supply to support that demand could be affected by Project pumping. Irrigation water demand is estimated, as described below, using information from the *Final Recycled Water Feasibility Study* (Feasibility Study) (Carollo 2008). The Feasibility Study was developed cooperatively with the City of South San Francisco, the City of San Bruno, and the City of Brisbane, the SFPUC, and Cal Water. The Feasibility Study encompasses South San Francisco, San Bruno, Brisbane, and Colma and evaluated evapotranspiration in the study area and applied standard irrigation use coefficients to estimate the irrigation demand of cemeteries and golf clubs in the region. The annual water demand was estimated to be 1.7 af per acre of irrigated turf.

The Feasibility Study also estimated peak demand for irrigation water. Peak demand is important, because the need for irrigation water supply varies greatly throughout the year, with peak demand occurring on the hottest day of the hottest month. The peak month is estimated to require 20 percent of the total annual demand. The peak day is estimated to require 30 percent more than the average day in the peak month (Carollo 2008). Finally, golf clubs and cemeteries must be irrigated at night to accommodate daytime use by golfers and visitors and, therefore, must deliver the water over an approximately 12-hour period. As a result, peak demand is estimated be 0.0147 af/acre over a 12-hour period[20]. The acreage of potentially affected land uses was multiplied by this peak demand factor to determine the peak demand of each of the potentially affected irrigators, and the results are shown in Table 5.16-9 (Existing Irrigated Acreage and Estimated Peak Demand at Potentially Affected Land Uses).

TABLE 5.16-9
Existing Irrigated Acreage and Estimated Peak Demand at Potentially Affected Land Uses

Land Use	Irrigated Acreage (acres) [(a)]	Estimated Peak Demand (af per 12-hour period)
Woodlawn Memorial Park	50	0.7
Italian Cemetery	28	0.4
Eternal Home Cemetery	13	0.2
Olivet Memorial Park	57	0.8
Salem Cemetery, Hills of Eternity and Home of Peace	43	0.6
Cypress Lawn Memorial Park	146	2.2
Holy Cross Cemetery	150	2.2
California Golf Club	120	1.8

Note:

(a) Acreage from SFPUC 2010b

[20] The Feasibility Study (Carollo 2008) estimated that annual irrigation demand for turf in the Colma area is 1.7 af/acre and peak month demand is 20 percent of that – or 0.34 af/acre. An average day in the peak month is 1/30 of the monthly demand, or 0.011 af/acre. The peak day of the peak month is 30 percent higher than the average day, or 0.0147 af/acre. This water must be provided in a 12-hour period to accommodate nighttime irrigation.

The San Francisco Golf Club, the Olympic Club, and Lake Merced Golf Club use mostly recycled water to irrigate their golf clubs, but also use groundwater. Table 5.16-10 (Existing Average Annual Recycled Water and Groundwater Use and Estimated Peak Demand at Potentially Affected Land Uses that Use Recycled Water) shows average annual recycled water deliveries and groundwater use from 2005 to 2008 at these golf clubs (LSCE 2010). Peak groundwater demand (rather than annual average groundwater demand) is not known; therefore, peak demand is estimated using factors from the Feasibility Study to estimate total peak daily demand for both recycled water and groundwater. This estimated total peak daily demand is multiplied by the annual groundwater percentage to estimate the peak demand for groundwater over a 12-hour period[21]. Table 5.16-10 shows the estimated peak groundwater demand for each of the three golf club sites receiving recycled water.

TABLE 5.16-10
Existing Average Annual Recycled Water and Groundwater Use and Estimated Peak Demand at Potentially Affected Land Uses that Use Recycled Water [(a)]

Land Use	Average Annual Recycled Water Use 2005-2008 (af)	Average Annual Groundwater Use 2005-2008 (af)	Estimated Peak Day Demand for Groundwater (af per 12-hour period)
San Francisco Golf Club [(b)]	134	39	0.3
Olympic Club	321	10	0.1
Lake Merced Golf Club [(c)]	94	21	0.2

Notes:

(a) Data for the average annual recycled water use and groundwater use are taken from Final Task 8B Technical Memorandum #1, Hydrologic Setting of the Westside Basin (LSCE 2010). Slightly different data were subsequently made available for the San Francisco and Lake Merced golf clubs in the Final - 2011 Annual Groundwater Monitoring Report (SFPUC 2012e), which provides slightly different data for the years 2005 through 2008 and additional data for the year 2009. It is unknown which data from 2005 to 2008 are more accurate. The difference in groundwater use presented in the two sources is small and would not result in a change in the level of significance before or after mitigation compared to the results presented in this section, and therefore the earlier data from Technical Memorandum #1 have been used.

(b) Groundwater use for San Francisco Golf Club available for 2005, 2007 and 2008 from LSCE 2010.

(c) Groundwater use for Lake Merced Golf Club available only for 2005 and 2007 from LSCE 2010.

Approach to Analysis

Well interference could occur due to Project-related pumping in a manner that would result in a lowering of the local groundwater to a level where the production rate of preexisting nearby wells would drop to a level that would not fully support existing or planned land uses. For purposes of this analysis, a significant impact would result if the Project were to cause groundwater levels to decrease such that (1)

[21] For example, average annual combined recycled water and groundwater demand at San Francisco Golf Club is 172.4 af and peak month demand is 20 percent of that, or 34.5 af. An average day in the peak month is 1/30 of the monthly demand, or 1.15 af. The peak day of the peak month is 30 percent higher than the average day, or 1.5 af. The annual percentage of the total 172.4 af water use that is supplied by groundwater is 39/172.4, or 22 percent. The estimated peak groundwater daily demand is 22 percent of 1.5 af or 0.3 af.

the pump discharge rates of existing irrigators' wells decrease substantially enough that existing or planned land uses would not be fully supported, or (2) groundwater levels fall below the top of the well screen of existing irrigators' wells, resulting in decreased pump discharge rates and potential damage to the well that are substantial enough that existing or planned land uses would not be fully supported. The former cause of well interference is analyzed quantitatively and the latter cause is analyzed qualitatively, as described below.

Pump Discharge Rates at Existing Irrigators' Wells

The purpose of this analysis is to determine the extent to which groundwater levels at existing irrigators' wells would be decreased by the Project, thereby resulting in decreased pump discharge rates substantial enough that existing or planned land uses would not be fully supported. Groundwater level changes that are predicted to be caused by the Project are estimated by combining regional and localized groundwater level changes. Regional groundwater level changes during operation of the Project would include groundwater level decreases caused by pumping multiple Project wells and Partner Agency wells, as well as groundwater level increases caused by in-lieu recharge occurring when Partner Agency wells are not pumping groundwater. Localized groundwater level decreases would be caused by pumping nearby individual Project wells. Modeling conducted for this Project predicts that for 68 to 83 percent of the years during the 47-year simulation period (depending upon the location in the Basin), the Project would result in increased groundwater levels relative to levels predicted under modeled existing conditions (Fugro 2012a).

At each existing irrigation well, regional groundwater levels at the end of the modeled design drought are estimated for the Project based on the Project's hydrologic sequence of Put Years, Hold Years, and Take Years, as described above and in Chapter 3, Project Description, Section 3.8.1 (Operating Agreement). Calculation of regional groundwater level changes during Put Years and Take Years is based on groundwater level monitoring data collected as part of the SFPUC's In-Lieu Recharge Demonstration Study and proposed changes in pumping during Put Years and Take Years. Indicative regional groundwater level decreases during Hold Years and every year of the existing conditions are based on results of the Westside Basin Groundwater Model. (Fugro 2012a)

Localized drawdowns are combined with the regional groundwater levels to account for localized effects from pumping nearby proposed Project wells. Local drawdown caused by Project pumping is estimated using the Theis equation, a standard method for calculating well interference effects. Using the Theis equation, groundwater level declines at the existing irrigators' wells were calculated based on aquifer tests in Daly City and San Bruno in 2003 and adjusted to reflect aquifer conditions. (Fugro 2012a)

Combining localized drawdowns and regional groundwater levels results in estimates of groundwater levels at wells during droughts (Take Years). The groundwater level with the Project would be at its lowest at the end of the design drought.

Lowered groundwater levels increase pumping lift and decrease pump discharge rates. During operation of the Project, pump discharge rates at affected existing irrigation wells are estimated to have the greatest decreases at the end of the design drought when groundwater levels are estimated to be lowest. The impact of the Project on a given pump's discharge rate is calculated at the end of the design drought as the difference in the pump's discharge rate with and without the Project.

Pump discharge rates at each existing irrigation well are calculated based on the estimated groundwater level at the end of the design drought for both modeled existing conditions and for the Project scenario.

To determine the ability of the well or wells to support a land use, the estimated pump discharge rate in gpm is converted to the production capacity of the well over a 12-hour irrigation period in acre-feet. The 12-hour capacity for each well is calculated by multiplying the pumping discharge rate in gpm by the number of minutes in 12 hours, or 720 minutes. The 12-hour production capacity for each potentially affected land use is calculated by totaling the 12-hour capacities of all existing primary, active, and secondary wells serving the land use.

If primary, active, and secondary wells together cannot supply the estimated peak demand for a land use over a 12-hour period (nighttime irrigation) at the end of the design drought, due to well interference from the Project, then well interference impacts would be significant. In the case where the total capacity of existing primary, active, and secondary wells for a land use cannot supply the estimated peak demand under modeled existing conditions, the existing supply is only marginally adequate. Under these conditions, if well interference from the Project would cause any reduction in pumping capacity, the effect would be significant.

Well Screen Elevations at Existing Irrigators' Wells

The purpose of this analysis is to determine whether groundwater levels would drop below the top of the well screen of existing irrigators' wells, thereby resulting in decreased pump discharge rates and potential damage to the well substantial enough that existing or planned land uses would not be fully supported. Groundwater levels that drop below the top of well screens result in decreases in pump discharge rates and can potentially lead to well or pump damage. Both static groundwater levels and pumping groundwater levels are considered when evaluating whether the Project would cause groundwater levels to drop below the top of the well screens of existing irrigators' wells. The static groundwater level is the level when the well is not being pumped; the pumping groundwater level is the level when the well is pumping[22].

If predicted groundwater levels fall substantially below the top of the well screen due to the Project at the end of the design drought – and those levels are predicted to remain above the top of the well screen

---

[22] Both pumping and static groundwater levels are relevant when considering mitigation options. Pumping groundwater levels that drop below the top of well screen can result in both additional decreases in pump discharge rates and well or pump damage. Although higher than pumping groundwater levels, static groundwater levels are also important to consider because well owners have much less control over static groundwater levels than pumping groundwater levels. If groundwater levels drop below the top of the well screen only when the well is pumping, well owners potentially can lower the pump or install a new pump to maintain groundwater levels above the well screen. Although these changes may result in a decreased pump discharge rate, the rate may still be able to meet demand while eliminating the risk of well or pump damage. Similar pump management options are not available to the well owner if static (i.e., non-pumping) groundwater levels drop below the top of well screens. In this case, the increased risk of damage cannot be addressed by the well owner without more involved modifications to the well or well replacement.

under modeled existing conditions – then the risk of damage to the well or pump due to the Project may eventually prevent the well from meeting demand, and well interference would be significant.

Impact Discussion and Significance Determination

During wet and normal years, pumping from the GSR wells would be minimal (0.04 mgd to exercise the wells) and well interference effects would not result. During these years, groundwater levels would be higher than levels without the Project, which would reduce pump lifts at the irrigation wells with corresponding increases in production capacities during these times. However, Project pumping would occur at the maximum proposed rate (i.e., 7.2 mgd) during dry years. At the end of the design drought, Project pumping would have continued at maximum levels for 7.5 years. Therefore, this analysis focuses on the well interference that could occur at the end of the design drought.

Table 5.16-11 (Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought) shows the projected static and pumping groundwater levels at the end of the design drought at the existing irrigators' wells, when the greatest groundwater level decreases would be expected to occur. Table 5.16-11 also shows which well facility sites could affect which existing irrigation wells.

TABLE 5.16-11
Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought

Note:

INA: Information not available. Information on the existing irrigators' wells that would allow calculation of impacts of the Project on production capacity is not available.

The estimated decrease from the Project at the end of the design drought compared to existing conditions is less for the pumping water levels than the static water levels. As discussed below, the predicted lower water levels during Project operations at the end of the drought, compared to modeled existing conditions, would result in a lower pump discharge capacity, which would reduce the drawdown. Since pumping depth to water is the static depth to water plus drawdowns, decreases for pumping water levels are less than static water levels. When the wells at the San Francisco Golf Club and Olympic Club are not being pumped (i.e., static condition), groundwater levels at the end of the design drought are projected to decrease by approximately 14 feet due to the Project; when the wells are active (i.e., pumping condition), groundwater levels are projected to decrease approximately 4 to 11 feet due to the Project. When the wells at the other golf clubs and cemeteries are not being pumped (i.e., static condition), groundwater levels at the end of the design drought are projected to decrease by 85 to 169 feet due to the Project; when the wells are active (i.e., pumping condition), groundwater levels are projected to decrease by 81 to 147 feet due to the Project.

The Project pumping and resulting groundwater level decreases at the end of the design drought are projected to affect the pump discharge rates of existing irrigators' wells as shown in Table 5.16-12 (Estimated Pump Discharge Rate at the End of the Design Drought). Pump discharge rates at the San Francisco Golf Club and Olympic Club wells are projected to decrease by approximately two to four percent as a result of Project pumping. Pump discharge rates at the other golf clubs and cemeteries are projected to decrease by 10 to 87 percent. Higher percentage declines predicted at some wells are due to the characteristics of the specific pumps installed in the well, which can magnify the effect of lower water levels.

Notes:

(a) The predicted large percentage reduction is largely due to the particular pump installed in the well as opposed to differences in water level declines (e.g., decline is about 15 feet more at Woodlawn than at other cemetery wells).

(b) The difference in pumping capacity decline predicted at the two California Golf Club wells is mostly a function of the characteristics of the pump curve for the specific pumps installed in each well.

INA: Information not available. Information on the existing irrigators' wells that would allow calculation of impacts of the Project on production capacity is not available.

If primary, active, and secondary wells supporting a land use together cannot supply the peak demand for that land use over a 12-hour period (nighttime irrigation) due to reduced pump discharge rates from the Project, then well interference impacts would be significant. For this analysis, Table 5.16-13 (Estimated Peak Demand and 12-Hour Production Capacities) compares the 12-hour production capacity at each golf club and cemetery to the estimated peak demand needed to maintain adequate irrigation for the land use.

TABLE 5.16-13
Estimated Peak Demand and 12-Hour Production Capacities

Land Use	Estimated Peak Demand (af per 12-hour period)	12-Hour Production Capacity for Primary, Active, and Secondary Wells (af)		Significant Impact relative to Pump Discharge Rates?	Significant Impact relative to Well Screen Elevations?[(a)]
		Existing Conditions	With Project

Note:

(a) Results for this column are taken from Table 5.16-14 (Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought), below.

(b) The predicted large decline in capacity from 1.0 to 0.1 is largely due to the particular pump installed in the well as opposed to differences in water level declines (e.g., decline is about 15 feet more at Woodlawn than other cemetery wells).

(c) The predicted pumping capacity decline at the two California Golf Club wells is mostly a function of the characteristics of the pump curve for the specific pumps installed in each well.

INA: Information not available. Information on the existing irrigators' wells that would allow calculation of impacts of the Project on production capacity is not available.

If water levels were to fall below the top of screen, there could be decreases to discharge capacities in addition to those estimated in Table 5.16-13 and an increase in risk of damage to the well. Table 5.16-14 (Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought) compares the estimated depth to water at the end of the drought with the top of the well screen.

Note:

(a) Positive number indicates water level is above top of screen and negative number indicates water level is below top of screen.

INA: Information not available. Information on the existing irrigators' wells that would allow calculation of impacts of the Project on production capacity is not available.

At the Olympic Club and San Francisco Golf Club, the 12-hour pumping capacities are expected to meet or exceed their estimated peak demand even when Project pumping is at a maximum at the end of the design drought (see Table 5.16-13 [Estimated Peak Demand and 12-Hour Production Capacities]). In addition, static and pumping groundwater levels are not estimated to drop below the top of the screen at the Olympic Club and San Francisco Golf Club wells (see Table 5.16-13). Therefore, the Project impact at the Olympic Club and San Francisco Golf Club would be *less than significant*.

At the Home of Peace well, which also serves Salem Cemetery and Hills of Eternity Cemetery, the 12-hour pumping capacity is estimated to meet or exceed its estimated peak demand even when Project pumping is at a maximum at the end of the design drought (see Table 5.16-13 [Estimated Peak Demand and 12-Hour Production Capacities]). The pumping groundwater level at the recently constructed well at the Home of Peace Cemetery is estimated to drop below the top of the screen at the end of the design drought due to the Project, but only by six of the 140 feet of screen (see Table 5.16-14 [Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought]), which is unlikely to reduce the pumping capacity such that the well would not meet demand given that pumping capacity could be reduced another 40 percent and still meet peak demand. However, pumping groundwater levels dropping below the top of the screen increases the risk of well or pump damage. This risk results in the potential for the well to be unable to meet demand over the long term, if damage should occur. Therefore, the Project would have a *significant* impact relative to well interference at the Salem Cemetery, Hills of Eternity Cemetery, and Home of Peace Cemetery.

At Holy Cross Cemetery and Eternal Home Cemetery, the 12-hour pumping capacities are estimated to meet peak demand even when Project pumping is at a maximum at the end of the design drought (see Table 5.16-13 [Estimated Peak Demand and 12-Hour Production Capacities]). However, static groundwater levels at the end of the design drought are estimated to fall below the top of the screen by a substantial length of the screen at the Eternal Home Cemetery well due to the Project. Pumping groundwater levels at the end of the design drought at the Holy Cross Cemetery wells, in addition to the Eternal Home Cemetery well, are estimated to fall below the top of the screen by a substantial length of the screens due to the Project (see Table 5.16-14 [Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought]). Additional reductions in pumping capacities due to less of the screens providing water have not been quantified, but it is possible that 12-hour pumping capacities could be reduced more than estimated, such that peak demand would not be met. The Eternal Home site has a 10,000-gallon storage tank (Fugro 2012a), but that equates to only 0.03 af, which may not be enough storage to offset the additional reduction in pumping capacity due to less of the screen providing water. Therefore, the Project would have a *significant* impact relative to well interference at Holy Cross Cemetery and Eternal Home Cemetery.

At Woodlawn Memorial Park, Italian Cemetery, and the California Golf Club, pumping capacities are estimated to decline 41 to 87 percent[23] when Project pumping is at a maximum compared to modeled existing conditions at the end of the design drought (see Table 5.16-12 [Estimated Pump Discharge Rate at

---

[23] Greater decreases in pumping capacities were estimated for the Woodlawn Primary Well (87 percent) and California Golf Club Wells (41 and 78 percent) due to the specific characteristics of the pumps installed in these wells.

the End of the Design Drought]). As a result, the 12-hour pumping capacities under the Project are estimated to not meet the peak demand at these sites (see Table 5.16-13 [Estimated Peak Demand and 12-Hour Production Capacities]). In addition, estimates of static groundwater levels at the end of the design drought at the wells at Woodlawn Memorial Park, Italian Cemetery, and California Golf Club drop below the top of the screen due to the Project (see Table 5.16-14 [Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought]). The reduction in the effective screen length of the well could result in additional reductions in well capacities that have not been quantified and make it more likely that the well would not fully support existing land uses. Impacts relative to well interference would therefore be *significant* at the Woodlawn Memorial Park, Italian Cemetery, and California Golf Club.

The only cemetery or golf club that is estimated to have insufficient existing 12-hour pumping capacity for meeting peak demand at the end of the design drought would be Olivet Memorial Park (see Table 5.16-13 [Estimated Peak Demand and 12-Hour Production Capacities]). As a result, the existing groundwater supply pumped from this well for this land use is only marginally adequate at present and a 40 percent reduction of pumping capacity at this cemetery at the end of the design drought, as shown in Table 5.16-12 (Estimated Pump Discharge Rate at the End of the Design Drought), would prevent the well from fully supporting the existing land use. In addition, estimates of static groundwater levels at the end of the design drought at the Olivet Memorial Park wells show dewatering of a substantial amount of the well screen due to the Project (see Table 5.16-14 [Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought]). The reduction in the effective screen length of the well could result in additional reductions in well capacities that have not been quantified and make it more likely that the well would not fully support the existing land use. Therefore, the Project would have a *significant* impact at Olivet Memorial Park relative to well interference. However, the Project would result in increased groundwater levels relative to modeled existing conditions at the Olivet Memorial Park during 74 percent of the 47-year modeling period (Fugro 2012a). As a result, pumping capacity at Olivet Memorial Park would increase and make it more likely for the well to meet its estimated peak demand in those years.

Information about the size and type of pump is not available for the Cypress Lawn Memorial Park wells, so Project effects on pumping capacity cannot be quantified. However, groundwater levels due to Project pumping at the end of the design drought are estimated to be approximately 95 to 98 feet lower than under modeled existing conditions (see Table 5.16-11 [Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought]). This difference is similar to the differences estimated for wells at Woodlawn Memorial Park, Italian Cemetery, and California Golf Club, where reductions in well yield from the lower groundwater levels at the end of the design drought during Project operations are predicted to prevent the wells from fully supporting existing land uses. In addition, the estimated groundwater levels with Project pumping at the end of the design drought would likely dewater a substantial portion of the well screens of Cypress Lawn Memorial Park's well #3 (see Table 5-16-11), which could add to the estimated reductions in well yield. Therefore, the Project would have a *significant* impact relative to well interference at Cypress Lawn Memorial Park.

Information about the size and type of pump is not available for the Lake Merced Golf Club wells, so Project effects on pumping capacity cannot be quantified as precisely as other wells. However, groundwater levels due to Project pumping at the end of the design drought are estimated to be approximately 87 feet lower than under modeled existing conditions (see Table 5.16-11 [Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought]). It is estimated that this decrease would reduce discharge rates of the Lake Merced Golf Club wells by 10 to 30 percent (Fugro 2012a).

Although it is unknown what discharge rate would result from this decrease, it is likely that the well could meet its estimated peak daily demand[24]. However, the estimated static groundwater levels with Project pumping at the end of the design drought would likely fall below the top of the well screen of the Lake Merced Golf Club well by a substantial length, increasing the risk of well or pump damage. This risk results in the potential for the well to be unable to meet demand if damage should occur. Therefore, the Project would have a *significant* impact relative to well interference at the Lake Merced Golf Club.

Evaluation of Three Alternate Well Sites

To evaluate the well interference impacts of operating the three alternate well sites, the analysis assumed that 16 wells would be operated, including Sites 17 (Alternate), 18 (Alternate), and 19 (Alternate), but not including Sites 1, 4, and 15. Given the locations of wells removed from the modeling scenario (two at the northern end and one at the southern end of the GSR Project area) versus the locations of the alternate wells (generally in the middle of the GSR Project area), the alternate well configuration would reduce drawdowns in the Daly City and San Bruno areas and increase drawdowns in the Colma and South San Francisco area (Fugro 2012a). This configuration would represent only one possible alternate configuration. However, this configuration demonstrates what could be viewed as a worst-case scenario for the Colma and South San Francisco areas, and the configuration with the preferred 16 wells as the worst-case scenario for the Daly City and San Bruno areas.

Therefore, the analyzed alternate configuration includes pumping from Sites 2, 3, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 17 (Alternate), 18 (Alternate), and 19 (Alternate). Under this alternate configuration, more Project pumping would occur in the Colma and South San Francisco areas and less Project pumping would occur in the Daly City and San Bruno areas. As a result, groundwater levels at the Olympic Club and San Francisco Golf Club wells at the end of the design drought are estimated to be higher than shown on Table 5.16-11 (Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought) (Fugro 2012a). Therefore, under this alternate configuration, the Project would still have a *less than significant* impact relative to well interference at the Olympic Club and San Francisco Golf Club.

Also under this alternate configuration, groundwater levels at the end of the design drought in the wells serving the Colma cemeteries and the California Golf Club are estimated to be lower than shown on Table 5.16-11 (Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought) (Fugro 2012a). Under the SFPUC's preferred configuration (i.e., wells at Sites 1 through 16), the Project would have a *significant* impact on the California Golf Club and the Colma cemeteries. Therefore, under the alternate configuration, the Project would still have a *significant* impact relative to well interference at the Colma cemeteries and California Golf Club.

---

[24] Although it is unknown what discharge rate would result from the projected groundwater level declines, the well would meet its estimated peak daily demand of 0.2 af if the resulting discharge rate is at least 104 gpm. Assuming a 30 percent reduction, the existing discharge rate would have to be 150 gpm or greater to meet demand with the Project. It is reasonable to assume that Lake Merced Golf Club has a pump with a discharge rate greater than 150 gpm, because wells at other golf courses in the Westside Groundwater Basin have existing discharge rates in the range of 200 to 970 gpm. Also, the well at the Lake Merced Golf Club was the sole source of irrigation water prior to recycled water becoming available.

Groundwater levels at Lake Merced Golf Club wells at the end of the design drought are estimated to be 21 to 22 feet higher than shown on Table 5.16-11 (Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought) under the analyzed alternate configuration (Fugro 2012a). However, static groundwater levels are estimated to still drop below the top of the well screen, and the Project would therefore still have a *significant* well interference impact at the Lake Merced Golf Club.

Mitigation Approach

As provided below, Mitigation Measure M-HY-6 (Ensure Existing Irrigators' Wells Are Not Prevented from Supporting Existing or Planned Land Use Due to Project Operation) establishes a performance standard to ensure that well interference impacts caused by the Project would be avoided or reduced to *less-than-significant* levels. The mitigation measure also requires a Monitoring Program at the existing irrigators' wells to provide reliable and timely data to determine if the performance standard is being met and requires the analysis of monitoring data twice a year during Take Years (i.e., when Project Wells are regularly pumping) to determine whether or not reduced pumping capacities at existing irrigation wells are found to occur as a result of the Project.

If the results of the Monitoring Program and biannual analyses during Take Years indicate that well interference impacts of the Project would cause the performance standard to be exceeded, then a list of example mitigation actions are provided that would maintain an uninterrupted supply of groundwater to the affected land use. Mitigation actions that may need to be implemented would vary depending on site-specific conditions at the existing irrigators' wells and a determination of the extent of the decrease in pumping capacity that is occurring due to Project operations and, therefore, the list of mitigation actions includes actions both at the existing irrigators' wells and also at the Project wells. Each action item may be suitable to address impacts on an existing irrigator's well, either alone or in combination with one or more of the other mitigation actions. Each of the mitigation actions, or a combination of mitigation actions, may be feasible and effective in particular circumstances. However, not every one of the mitigation actions alone are anticipated to be feasible and effective at reducing impacts to *less-than-significant* levels in all circumstances, because the irrigation systems, wells, and parcels where the existing irrigators' wells are located are all different and may experience a range of impacts due to Project-caused well interference. Either one or a combination of the mitigation actions identified in Mitigation Measure M-HY-6 is anticipated to reduce impacts to a *less-than-significant* level.

Mitigation actions #1, Improve irrigation efficiency, and #2, Modify irrigation operations, would install measures such as more-efficient sprinkler heads or soil-moisture sensors and would modify operations, for example, through the use of longer irrigation cycles or revised scheduling of irrigation to respond to evapotranspiration data. These actions would tend to mitigate impacts if the irrigation well capacity were only slightly less than the performance standard due to Project pumping. Effectiveness of the actions would vary depending on the design of the existing irrigation system, and would not be expected to be feasible and effective in all cases. (SFPUC 2012c)

Mitigation actions #3, Redistribute GSR pumping, and #4, Reduce GSR pumping, would reduce the rate of groundwater level decline in an affected area by redistributing Project pumping to other areas or by reducing Project pumping. Redistribution of GSR pumping would not be undertaken where the resulting groundwater levels would then decline more than what was originally predicted to be caused by the Project by modeling, therefore, redistribution would be effective at reducing well interference impacts at existing irrigation wells only if some GSR wells are determined to be capable of producing more water with less drawdown than originally predicted (SFPUC 2012a, 2012c). Reduction of GSR pumping would be effective at reducing well interference impacts at existing irrigation wells to *less-than-significant* impacts, but this would be an interim measure, implemented until such time as an alternate measure can be implemented that also mitigates the impact to *less-than-significant* levels.

Mitigation actions #5, Lower pump in irrigation well, and #6, Lower and change pump in irrigation well, would lower the well pump to accommodate groundwater level fluctuations induced by Project pumping that exceed historic levels, or lower and replace the well pump using a more suitable pump for the conditions that are encountered in order to meet demands. These actions would mitigate impacts if the irrigation well capacity were moderately less than the performance standard due to Project pumping. Effectiveness of the actions would vary depending on the design of the existing irrigation well and type of pump used. The actions would also be dependent upon the existing irrigation well being deep enough to accommodate lowering of the pump. For this reason, these actions would not necessarily be feasible and effective in all cases. (SFPUC 2012c)

Mitigation action #7, Add storage capacity for irrigation supply, would add storage; for example, an above-ground tank of 20,000 gallons, which could be up to 20 feet in height. Increased storage capacity may provide the ability to meet peak flow rates that would otherwise be less than the performance standard, in that irrigators could store the additional water in the tank to use during the period of peak demand. It appears likely that each of the existing irrigators could feasibly place a tank on their property, however, increased storage may not be sufficient to meet the performance standard if the reduced well capacity due to the Project is large. (SFPUC 2012c)

Mitigation action #8, Replace irrigation well, would be effective at any of the affected land uses, because the replacement well could be constructed deep enough at each of the cemeteries or golf clubs to operate under the new conditions and thereby meet peak irrigation demand. This mitigation action would be feasible from the standpoint that each of the existing irrigators' well sites has available areas in which a replacement well could be installed, and groundwater resources are deep enough in the area of each irrigator to drill deeper wells (SFPUC2012d). Well permits would need to be obtained from the San Mateo County Department of Environmental Health or City of Daly City, depending on the location of the replacement well. The County's and Daly City's well ordinances provide that granting of a well permit is dependent upon the well meeting the health, safety, and welfare of its citizens. Because wells that would be installed under Mitigation action #6 would replace existing and currently operational irrigation wells, it is expected that the required well permits would be issued by the County and Daly City.

Mitigation action #9, Replace irrigation water source, would provide a new temporary source of water only until another mitigation action could be implemented. Water would be provided via temporary aboveground pipes from Partner Agency or SFPUC supply from distribution or transmission pipelines close to the location where additional irrigation supplies are needed. This action would not be implemented on a permanent basis.

Implementation of Mitigation Measure M-HY-6 (Ensure Existing Irrigators' Wells Are Not Prevented from Supporting Existing or Planned Land Use Due to Project Operation) would depend upon the willingness of the well owner to participate in the monitoring program and to allow the SFPUC to install a replacement well or take other corrective action as mutually determined necessary to address the impacts from the Project and meet the performance standard. Therefore, while Mitigation Measure M-HY-6 could reduce the impacts of well interference to a level where existing and planned land uses would continue to be fully supported, its implementation cannot be assured at this time. Nevertheless, with participation in the monitoring program and concurrence to allow implementation of the mitigation actions by all affected existing irrigation well owners, the well interference impacts would be less than significant with mitigation. However, because such assurance cannot be attained prior to Project approval, Impact HY-6 with implementation of Mitigation Measure H-HY-6 is deemed at this time to be *significant and potentially unavoidable with mitigation*.

Mitigation Measure M-HY-6: Ensure Existing Irrigators' Wells Are Not Prevented from Supporting Existing or Planned Land Use Due to Project Operation

This mitigation measure is organized into five sections, as follows:

- Performance standard,
- Mitigation Actions to be Undertaken to Meet the Performance Standard,
- Method for Determining Whether Loss of Pumping Capacity at an Existing Irrigator's Well Is Due to the Project,
- Existing Irrigator Well Monitoring Program, and
- Definitions of terms

Performance Standard: The SFPUC will ensure that the production capacity at existing irrigators' wells is equivalent to the existing production capacity of the wells or is sufficient to meet existing and planned peak irrigation demand at the land use, whichever is less, provided that the loss of capacity at the existing irrigators' wells is reasonably expected to have been caused by the Project.

If the production capacity at an existing irrigator's well is shown to drop below this performance standard due to the Project, measures to avoid or reduce Project contributions to the loss of capacity or measures to meet irrigation needs will be implemented by the SFPUC. The SFPUC will implement these measures, or a combination thereof, so that water supply provided to the land use by the existing irrigators' well(s) is not interrupted. The method for determining whether the loss of pumping capacity is attributable to the Project is described in detail below.

In order to implement one or more of the mitigation actions, it is necessary to, and the SFPUC shall, conduct monitoring at existing irrigators' wells to determine whether the performance standard is being met. The monitoring program is described in detail below.

Mitigation Actions to be Undertaken to Meet the Performance Standard: The SFPUC shall, in cooperation with the existing irrigators, implement actions to meet the performance standard in this mitigation measure when the production capacity of an existing irrigator's well drops below the performance standard. The following mitigation actions are examples of the type of actions that, alone or in combination, will avoid or reduce Project impacts, depending on the circumstance:

1. *Improve irrigation efficiency.* Seek ways to reduce applied water demand through irrigation efficiency measures. For example, sprinkler nozzles can be replaced with more efficient models, sprinklers can be added to achieve more evenly distributed irrigation, and installation of soil-moisture sensors can aid in irrigation scheduling.

2. *Modify irrigation operations.* Seek ways to modify operations to accommodate reduced well capacity. For example, use longer irrigation cycles to meet the same irrigation demand or use evapotranspiration data to modify irrigation scheduling.

3. *Redistribute GSR pumping.* Seek to reduce the rate of groundwater level decline in the affected area by redistributing Project pumping to other areas; however, in no case would redistribution be undertaken where the resulting groundwater levels would then decline more than what was originally predicted to be caused by the Project by modeling. The bi-annual analyses of data from the Monitoring Program would continue while this action is undertaken. The action would cease when the data analysis shows that the performance standard is met without continued redistribution of GSR pumping.

4. *Reduce GSR pumping.* Seek to reduce the rate of groundwater level decline through a reduction in Project pumping (including a cessation in Project pumping at wells in the vicinity of existing irrigation wells). The bi-annual analyses of data from the Monitoring Program would continue while this action is undertaken. The action would cease when the data analysis shows that the performance standard is met without continued reduction of GSR pumping.

5. *Lower pump in irrigation well.* A pump may be lowered to accommodate water level fluctuations induced by Project pumping that exceed historic levels.

6. *Lower and change pump in irrigation well.* A pump may be replaced and set to a lower depth to accommodate new head conditions because of lowered water levels induced by Project pumping.

7. *Add storage capacity for irrigation supply.* Under certain conditions, storage may be added (e.g., an above-ground tank) to offset reduced well capacity caused by Project pumping. The availability of storage capacity (or of increased capacity) can provide an ability to meet peak flow rates that are otherwise reduced by lowered water levels.

8. *Replace irrigation well.* An existing irrigation well may be replaced with a new well which may be designed with different screen intervals or depth. The new irrigation well could therefore access additional groundwater resources at new depths in the aquifer.

9. *Replace irrigation water source.* In the event that the preceding options cannot be implemented without causing an interruption in the irrigation supply, a temporary replacement water supply source would be provided from the regional water system or Partner Agency distribution system via temporary aboveground pipes close to the location where additional irrigation supplies are needed until another mitigation option(s) is implemented.

Method for Determining Whether Loss of Pumping Capacity at an Existing Irrigation Well(s) Is Due to the Project. Any loss in production capacity of an existing irrigation well(s) is assumed to be caused by the Project if: 1) it is temporally correlated with the onset of increased Project pumping; 2) it occurs in an area predicted in this EIR to be affected by well interference; 3) static groundwater levels have dropped; 4) pumping groundwater levels have not dropped more than static groundwater levels (if pumping groundwater levels drop more than static groundwater levels it could indicate the drop in production capacity is due to increased well inefficiency and not due to the Project); or 5) no other obvious reason exists for the drop in production capacity If another reason is identified, it will be based on the written professional opinion of a certified hydrogeologist or professional engineer with expertise in groundwater hydrology that will be submitted to the San Francisco Planning Department's Environmental Review Officer (ERO), or designee, for review and concurrence. The ERO may require the SFPUC to hire an independent expert to advise the ERO.

To support this determination, the SFPUC will develop at least the following information:

- *Item 1. It is temporally correlated with the onset of increased Project pumping.* The SFPUC will develop a graph that shows the pumping of Project and Partner Agency wells within 1.5 miles of the existing irrigator's well over time, compared to the production capacity of the existing irrigator's well over the same period.
- *Item 2. It occurs in an area predicted to be affected by well interference.* The SFPUC will calculate the cone of depression, using the same methodology as used in evaluating the impact in the EIR, at Project and Partner Agency wells within 1.5 miles of the existing irrigator's well, as well as at the existing irrigator's well.
- *Items 3 and 4. Static water levels have dropped and pumping water levels have not dropped more than static water levels*. The SFPUC will develop a graph showing the difference between static and pumping water levels at the existing irrigator's well over time.
- *Item 5. Another reason exists for the drop in production capacity.* If the SFPUC believes that the drop in production capacity of the existing irrigation well(s) is caused by factors other than the Project – and the owner of the existing irrigation well(s) disagrees – then the SFPUC will have a certified hydrogeologist or professional engineer with expertise in groundwater hydrology prepare documentation regarding the reasons for the drop in production capacity and submit this documentation to the San Francisco Planning Department's ERO, or designee, with a copy to the existing well owner. The ERO may require the SFPUC to hire an independent expert to advise the ERO.

In addition, the following Monitoring Program will assist the SFPUC in obtaining the data necessary to support the determination of probable cause for any groundwater level decreases at an existing irrigator's well.

Existing Irrigation Well Monitoring Program. The SFPUC will monitor short- and long-term changes in groundwater conditions and operations at existing irrigators' wells. This Existing Irrigator Well Monitoring Program applies to existing well owners who choose to participate in the program. Participation in this monitoring program is assumed to be necessary for the mitigation actions to be effectively implemented by the SFPUC at the affected well.

At least 18 months prior to the commencement of pumping of Project wells, the SFPUC shall contact existing irrigators with information about the monitoring program. To participate in the program, existing irrigators will complete a registration form and an agreement with the SFPUC. The monitoring program will include the installation of a flow meter to allow for daily well production volumes to be recorded and a groundwater level transducer/data logger (a device for automatically detecting and recording groundwater levels) for measuring groundwater levels. Baseline monitoring of flow meter data and groundwater level data in the existing irrigators' well will occur among willing participants for at least one year prior to pumping the Project wells. In addition to baseline monitoring of well production and groundwater levels, pumping tests will be conducted prior to commencement of pumping Project wells to collect baseline data on pump and well performance. The pumping tests will collect data on well capacity and drawdown, well specific capacity, pump efficiency and head-capacity characteristics, sand content, and selected water quality parameters.

The SFPUC shall also collect any existing information and data available regarding the existing irrigator's well from the well owner, including any estimates or measurements of historical, existing, and planned land and water use (e.g., driller's logs, water level data, pumping records, acres irrigated) to provide information upon which to evaluate the performance of the existing irrigator's well over time and to establish baseline operating conditions. When there is an opportunity to open an existing irrigator's well (such as when a pump is removed by a well owner), the SFPUC may seek to conduct video log surveys in wells to determine the condition of the well structure. The monitoring effort will continue through the life of the Project, unless canceled by the well owner as part of the well owner's decision to remove itself from the monitoring program. Continued participation in this monitoring program is assumed to be necessary for the mitigation actions to be effectively implemented by the SFPUC at the affected well. Periodic re-testing of a well may occur as prompted by the need to evaluate performance throughout the life of the Project. If there is uncertainty or disagreement about whether the Project is responsible for a loss in production capacity at an existing irrigator's well, the SFPUC shall undertake more frequent monitoring and/or testing to help resolve the disagreement.

Data from the water level transducers/data loggers and flow meters shall be recorded daily during the first year. Following the first year of data collection, the frequency may be modified (e.g., as prompted by a need to evaluate pump and/or well performance to determine effects of the Project). The SFPUC shall provide participants with 14-day advance notice for the site visit(s) that would be scheduled within a 48-hour window.

Data shall be analyzed two times each year during Take Periods when Project wells are pumping regularly. The first data analysis period shall end April 30th when production capacity can be compared to peak demand prior to the peak demand period. The second data collection period shall end October 30th when groundwater levels will likely be lowest at the end of the peak irrigation season and production capacity of the well would be at its lowest. The data shall be compiled and analyzed by SFPUC's certified hydrogeologist or professional engineer with expertise in groundwater hydrology by June 30th and January 15th for the two data analysis periods. The data collected from each existing irrigator's well shall also be shared with the well owner upon request. In Project Put and Hold Periods, data shall be analyzed once per year for the data collected through October with analysis completed by January 15th.

Definition of Terms

Existing or planned land use. All existing and planned land uses served by existing irrigators' wells are related to turf irrigation. The only planned known (future) land use is the potential expansion of the Holy Cross Cemetery to include up to an additional 30 acres of irrigated turf.

Existing well capacity. Existing well capacity is the production capacity of the existing irrigator's well during the 12-month monitoring period prior to operation of the Project. The well capacity will be determined by the Monitoring Program described herein.

Peak irrigation demand. Peak irrigation demand is defined either as the actual peak irrigation demand determined from well production records obtained by the Monitoring Program described herein or as identified in Table M-HY-6 (developed from Table 5.16-14 [Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought] of the EIR), whichever is agreed to by the parties.

TABLE M-HY-6
Existing or Planned Peak Irrigation Demand at Sites with Significant Impacts Due to Project Operation

Irrigation Site	Existing and Planned Peak Demand[(a)] (af per 12-hour period)	
	Existing	**Planned**
Lake Merced Golf Club	0.2	0.2
Woodlawn Memorial Park	0.7	0.7
Italian Cemetery	0.4	0.4
Eternal Home Cemetery	0.2	0.2
Olivet Memorial Park	0.8	0.8
Salem Cemetery, Hills of Eternity and Home of Peace	0.6	0.6
Cypress Lawn Memorial Park	2.2	2.2
Holy Cross Cemetery	2.2	2.24
California Golf Club	1.8	1.8

Note:

(a) These values are taken from Tables 5.1-2 (Model Input – Pumping Assumptions for Modeling Scenarios), 5.16-9 (Existing Irrigated Acreage and Estimated Peak Demand at Potentially Affected Land Uses), and 5.16-10 (Existing Average Annual Recycled Water and Groundwater Use and Estimated Peak Demand at Potentially Affected Land Uses that Use Recycled Water) in the Draft EIR.

af = acre-feet

Production capacity. Production capacity of a well is the quantity of water that can be produced by a well in a 12-hour period. Production capacity will be calculated based on daily production, as measured by the flow meter, divided by pumping duration, as measured by the flow meter, multiplied by 12 hours.

Existing irrigators' wells. The existing wells that support the following land uses are the only wells that meet the definition of existing irrigators' wells for the purposes of this mitigation measure: Lake Merced Golf Club, Woodlawn Memorial Park, Italian Cemetery, Eternal Home Cemetery, Olivet Memorial Park, Home of Peace Cemetery, Cypress Lawn Memorial Park, Holy Cross Cemetery and the California Golf Club. Existing wells are those wells that are in operation prior to the approval of the Project.

Impact Conclusion: Significant and Unavoidable with Mitigation

Impact HY-7: Project operation would not result in substantial land subsidence due to decreased groundwater levels in the Westside Groundwater Basin where the historical low water levels are exceeded. (Less than Significant)

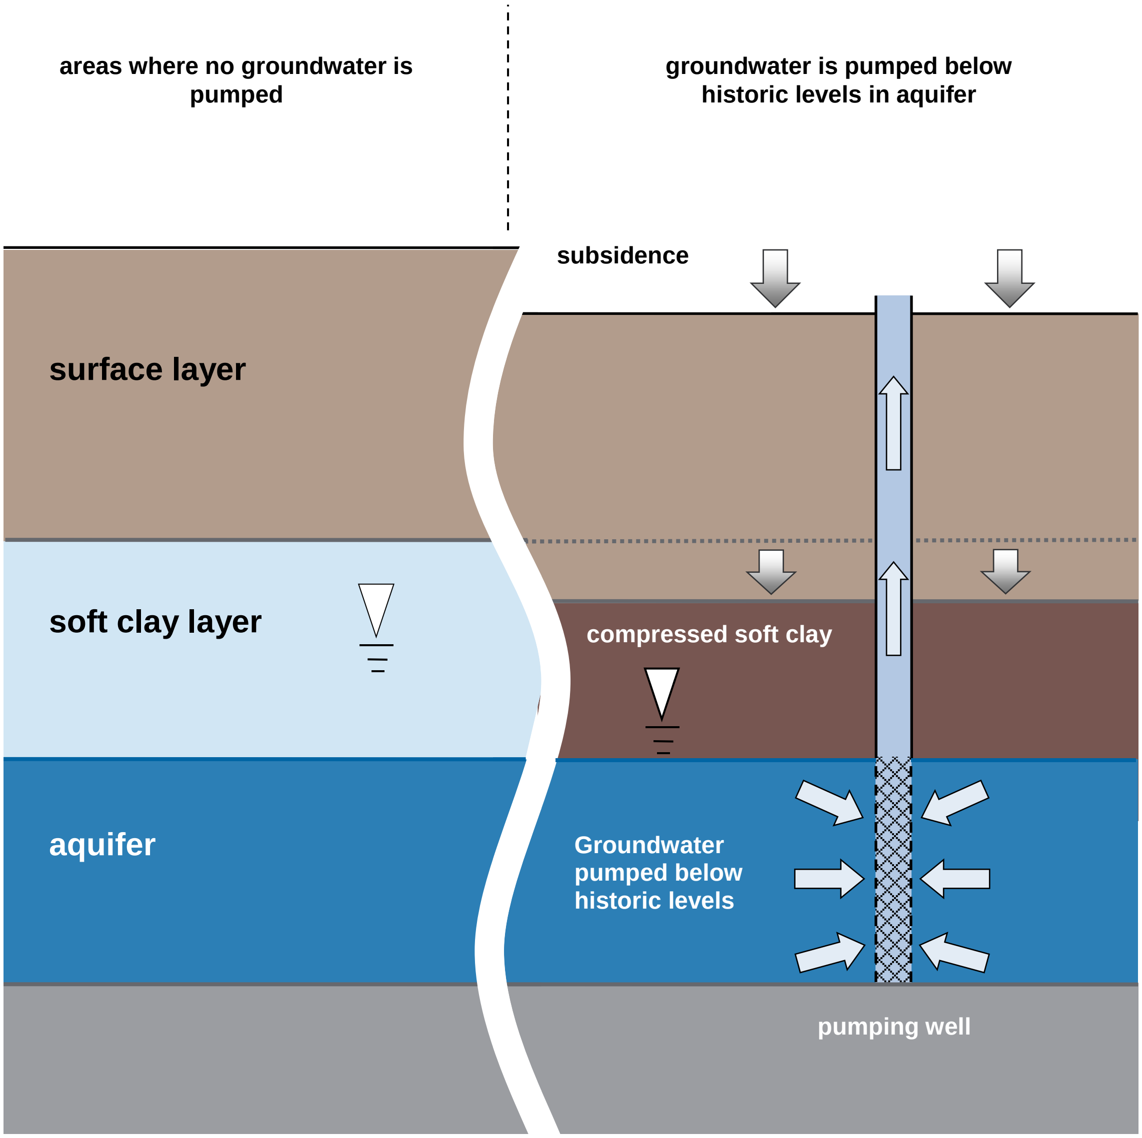
Description of Land Subsidence

Land subsidence is a gradual settling or sudden sinking of the earth's surface due to subsurface movement of earth materials (Galloway et al. 1999). While land subsidence can result from a number of processes, subsidence from groundwater pumping is the focus of the analysis for the Project. Land subsidence due to groundwater pumping can occur when groundwater elevations are lowered, and water drains out of an aquifer or clay layers that are within or between aquifers.

Subsidence in granular materials, such as sand and gravel that typically comprise the water-bearing portion of an aquifer, is generally minor and can be reversed when groundwater levels are raised again. However, as groundwater drains from the clay layers, there is less water supporting the clay particles and the clay layers can compress or compact. This can be a slow process, occurring over several months, or even years. With sufficient time, the magnitude of the compression can be great enough to result in a measurable, permanent lowering or subsidence of the ground surface (see Figure 5.16-8 [Subsidence Schematic]). Clays are far more compressible than sands or gravels; therefore, it is the presence of thick clays, rather than sands or gravels that indicates a potential for subsidence.

Approach to Analysis

Operation of the Project could cause land subsidence if Project-related groundwater pumping were to result in decreased groundwater levels in the Westside Groundwater Basin that are lower than the historic low groundwater levels for an extended period of time. Clay layers that are located above the historic low groundwater levels have already been drained of water and have already compressed, if they were susceptible to compression, as a result of long-term historic pumping in the Basin. This initial compaction of clay layers tends to be permanent (Fugro 2012b). Therefore, future land subsidence that could occur due to the Project would result only if historic low groundwater levels were exceeded. This analysis assumes that if predicted groundwater levels were to drop below historical low levels, they would be maintained at these low levels long enough to induce subsidence.



Subsidence Caused by Groundwater Pumping

Water Levels

Subsidence Schematic

Regional Groundwater Storage and Recovery Project

Figure 5.16-8

This page left intentionally blank

This is a conservative assumption that results in reporting the maximum amount of possible subsidence. The relevant factors that influence the expected amount of subsidence due to Project operation include:

- The extent to which groundwater levels are decreased by the Project compared to predicted groundwater levels for modeled existing conditions;
- The presence and thickness of clay layers or clayey sand layers;
- The compressibility of the clay or clayey sand layers; and
- The amount of time low groundwater levels are maintained. This analysis assumes low groundwater levels are maintained long enough to induce the maximum possible subsidence.

Anticipated subsidence from Project operations was estimated using the following methodology (Fugro 2012b; Fugro 2012d):

Four locations within the Westside Groundwater Basin were selected as representative locations to estimate the potential extent of subsidence due to the Project. These locations were selected based on a review of the basin geology. These four sites were considered representative of anticipated subsidence, because subsidence would tend to be greater at these sites due to thicker clay layers and greater drawdown of groundwater levels due to the Project. Selection of these four locations should not be interpreted to mean that potential subsidence would occur only around a specific well site; if subsidence were to occur, the results at these four locations would be representative of the maximum effect that could occur at any of the proposed well locations throughout the Basin.

- Two proposed well locations were selected for subsidence analysis in the North Westside Groundwater Basin: (1) the eastern side of Lake Merced (at the SFPUC's proposed SFGW Project Lake Merced Pump Station well site); and (2) the Sunset area of western San Francisco (at the SFPUC's proposed SFGW Project South Sunset Playground well site) (see Figure 5.1-3 [Location of Projects Considered in the Cumulative Analysis] in Section 5.1, Overview). These two sites were selected over other locations, such as Golden Gate Park, because of the greater prevalence of clay layers in the Sunset and Lake Merced areas compared to Golden Gate Park. This prevalence of clay layers would tend to result in greater estimated subsidence at the selected sites than in Golden Gate Park (Fugro 2012b). No subsidence calculations were performed for the South Sunset Well location relative to the Project, because the South Sunset well site is located too far from the GSR Project's well facility sites for there to be any subsidence effects from Project pumping; however, cumulative impact analyses on subsidence at the South Sunset Well location have been performed (SFPUC 2012b).
- Two proposed well locations were selected in the South Westside Groundwater Basin at Site 8 in the Town of Colma and Site 13 in the City of South San Francisco (see Figure 3-4 [Project Location Map – Central] in Chapter 3, Project Description). Site 8 was chosen for analysis because it appears to have clay layers that are representative of other well locations in the Colma area. Site 13 was selected over other locations due to the presence of multiple clay layers at shallow, intermediate, and deep depths. A very thick, intermediate-depth clay at this location makes this site particularly susceptible to subsidence. (Fugro 2012b)
- Historical low groundwater levels were estimated for each of the four sites, as subsidence is predicted to occur only when groundwater levels fall below historical low groundwater

levels. Historical low water elevations were estimated from historical groundwater level measurements where available. These data were supplemented with groundwater levels as estimated by the Westside Basin Groundwater Model. (Fugro 2012b)

- The difference between groundwater levels for the modeled existing conditions scenario and the Project scenario was obtained from the results of the Westside Basin Groundwater Model (Kennedy/Jenks 2012b). The lowest simulated groundwater levels predicted at each site were used for the subsidence analysis, resulting in the maximum differences that would be caused by the Project. Under the GSR Project, the lowest groundwater levels would occur at the end of the design drought. In the cumulative scenario, the lowest simulated groundwater levels are generally predicted to occur at the end of the 47-year simulation. (Fugro 2012b)
- Historical low groundwater levels, the difference between simulated groundwater levels for existing conditions and the Project, and clay properties were used to calculate subsidence. Subsidence was calculated using equations based on standard and well accepted soil mechanics theories detailed by Terzaghi et al. (Terzaghi et al. 1996). These equations relate the amount of subsidence to a clay's compressibility and thickness, as well as the change in groundwater levels.

The compressibility property of clay particles is one of the parameters required to perform the methodology described above. Knowledge of such values is limited and often imprecise; hence, so are the predictions of the extent of compaction and resulting subsidence. Site-specific laboratory test results of the compressibility of clays in the Westside Groundwater Basin were not available and, therefore, typical soil compressibility values of the Merced Formation (which underlies much of the Westside Groundwater Basin) were used in the estimations of subsidence.

Subsidence can affect surface features such as structures and pipelines, the extent of flooding, and drainage patterns. In general, structures, including pipelines, can withstand subsidence or settlement of six inches or less without damage (Lambe and Whitman 1969; SFPUC 2013d); therefore, projected subsidence of six inches or more is considered a significant impact on structures. Flood zones, as defined by the National Flood Insurance Program Regulations in 44 CFR Part 60.3(c)(10), are subject to revision when the Base Flood Elevation within a 100-year flood zone changes by one foot or more. The calculation and mapping of 100-year flood zones are generally not accurate to more than a one-foot elevation change, and changes to flood elevations of less than one foot should not be interpreted as necessarily causing an increased risk of flooding. Therefore, subsidence impacts on flooding are considered significant if projected subsidence exceeds one foot within a 100-year flood zone. Subsidence impacts on drainage patterns are considered significant if projected subsidence exceeds six inches.

Impact Discussion and Significance Determination

As described in Section 5.16.1.3 (Regional Groundwater Hydrology), historic subsidence in the Westside Groundwater Basin has not been documented. The fact that extensive historic groundwater extraction has resulted in associated declines in groundwater levels, but without any apparent substantial subsidence, suggests that the semi-consolidated Merced Formation sediments in the Westside Groundwater Basin have limited compressibility. Therefore, based on a conceptual understanding of the mechanisms required for land subsidence and the apparent lack of historic subsidence in the area, the potential for future subsidence due to the Project would likely be limited due to low compressibility of semi-consolidated Merced Formation sediments. (Fugro 2012b)

Estimates of land subsidence due to Project pumping were calculated at a Lake Merced site and GSR Sites 8 and 13 because these wells would be located where substantial clay layers occur, as described above under Approach to Analysis. Predicted groundwater levels at the end of the design drought are estimated to be lower than historic low groundwater levels by up to 58 feet at the Lake Merced site, by up to 173 feet at Site 8 in Colma, and by up to 174 feet at Site 13 in South San Francisco during operation of the Project. The difference between modeled existing conditions (i.e., conditions without the Project) and the estimated Project effects at the end of the design drought (i.e., conditions reflecting the lowest groundwater levels that would occur during operation of the Project) would be a decrease in predicted groundwater levels of up to 63 feet at the Lake Merced site, up to 149 feet at Site 8, and up to 151 feet at Site 13. (Fugro 2012b)

Table 5.16-15 (Estimated Subsidence due to Project Operations) shows the estimated subsidence due to the Project at the locations selected for the analysis. The estimated subsidence is based on the difference between groundwater levels for modeled existing conditions and the lowest groundwater levels that are projected to occur with the Project.

TABLE 5.16-15
Estimated Subsidence due to Project Operation (in inches)

Site ID	Estimated Subsidence
San Francisco, eastern Lake Merced	1.0
Colma, Site 8	2.9
South San Francisco, Site 13	3.4

Source: Fugro 2012b

The estimated subsidence due to Project operation ranges between 1.0 and 3.4 inches at the three representative locations where subsidence was calculated. This estimated subsidence due to Project operation is less than the significance threshold of six inches for impacts on structures and drainage patterns. Estimated subsidence due to project operation is also less than the significance threshold of one foot for flooding impacts on land within the 100-year flood zone. Therefore, subsidence due to Project operation would be *less than significant* relative to structures and pipelines, drainage patterns, and flooding.

Impact Conclusion: Less than Significant

Impact HY-8: Project operation would not result in seawater intrusion due to decreased groundwater levels in the Westside Groundwater Basin. (Less than Significant)

Description of Seawater Intrusion

Seawater intrusion refers to the migration of seawater into a freshwater aquifer and can occur when groundwater levels are lowered by pumping. Seawater intrusion becomes an environmental concern when the degradation of groundwater quality would make the groundwater potentially unsuitable for its identified use, or when inland surface water features are affected by the seawater, compromising habitats or uses of the surface water.

Where an aquifer is in direct hydraulic connection with an ocean or bay, the hydrologic zone where fresh groundwater and ocean saltwater meet—referred to as the saltwater/freshwater interface—is comprised of brackish water (a mixture of freshwater and saltwater) to saline water (water with high concentrations of salt). Aquifers that are not actively pumped typically provide freshwater outflow at the coast. Because this ocean outflow exerts seaward hydraulic pressure, it can generally hold seawater at equilibrium offshore from the coast and hinder its onshore advancement.

Seawater intrusion occurs when the freshwater-groundwater gradient declines toward the ocean or bay and the resulting seawater intrusion along the base of the aquifer is termed a "saltwater wedge" (see Figure 5.16-9 [Seawater Intrusion Schematic]). Because of the wedge-shaped boundary, the shallowest portion of the landward side of the saltwater/freshwater interface may remain relatively close to the point where the aquifer is in connection with the ocean or bay, but the deepest portion of the landward side of the saltwater wedge may extend further landward, even when freshwater is flowing to the ocean.

The extent of seawater intrusion into a freshwater aquifer is affected by the relative difference between water levels in the ocean or bay and the freshwater aquifer with which it is in direct hydraulic connection. The theoretical groundwater level necessary to prevent seawater intrusion is termed the "exclusion head." When groundwater levels drop below the exclusion head, the interface between the seawater and freshwater can theoretically move inland under certain conditions. The interface would move back toward the ocean or bay if groundwater levels were raised again. However, some of the salt can remain in the fresh water (even after the interface has moved back toward the ocean or bay), and this remaining saltwater can be difficult to remove (Kennedy/Jenks 2012c). The seawater/freshwater interface is not a sharp interface. Instead, diffusion and dispersion result in a transition zone at the interface where salt concentrations (typically measured as chloride or total dissolved solids [TDS]) range from values typical of freshwater at the leading edge (furthest inland) to those typical of seawater at the following edge (closest to the ocean or bay). The movement of the interface is controlled by changing conditions on the freshwater side of the interface. Seawater contains approximately 35,000 mg/L of TDS, which includes about 19,000 mg/L of chloride (USGS 2003). As discussed in Section 5.16.1.3 (Regional Groundwater Hydrology) under the sub-heading "Coastal Chloride Concentrations," the most recent chloride concentrations in the shallow water bearing zone, Primary Production Aquifer and Deep Aquifer in the North Westside Groundwater Basin are all below 160 mg/L (except at Monitoring Well LMMW-1S, as explained in 5.16.1.3 [Regional Groundwater Hydrology] under the sub-heading "Coastal Chloride Concentrations"). Therefore, there is a large contrast between the chloride concentrations in the seawater and the groundwater. In the North Westside Groundwater Basin, seawater intrusion has not been observed in coastal monitoring wells and the seawater/freshwater interface is assumed to be west of the shoreline.

Movement of the seawater/freshwater interface can be a slow process. The rate of movement depends on aquifer conditions, and seawater intrusion occurs only when the conditions that cause seawater intrusion are sustained for a sufficient period of time given the existing conditions. Fluctuating groundwater elevations can result in a wider transition zone.

Approach to Analysis

The Westside Basin Groundwater Model does not simulate seawater and freshwater flows or their interface but instead simulates groundwater-level changes. Therefore, the potential for seawater intrusion to occur in the Westside Groundwater Basin is evaluated using the results of the groundwater model in conjunction with groundwater contours, changes in flux to the ocean or bay, and analytical approaches to evaluate exclusion heads in the aquifer and the estimated rate of seawater intrusion (Kennedy/Jenks 2012c). If the Project were to not cause changes in these groundwater parameters in such a fashion that seawater intrusion would be more likely to occur, then the Project would not cause the chloride concentrations in groundwater to degrade to significant levels above 250 mg/L.

Three methods are used to estimate the potential for seawater intrusion at any location in the Westside Groundwater Basin:

- Comparing simulated groundwater elevations to calculated exclusion heads[25],
- Analyzing the changes in the simulated flux of groundwater flowing to the ocean, and
- Analyzing simulated groundwater contours.

This impact analysis does not discuss groundwater levels and quality at the Thornton Beach and Fort Funston monitoring locations because these monitoring points are located southwest of the Serra Fault, between the San Andreas Fault and Lake Merced, as described in the "Regional Geology" subsection of Section 5.16.1.3 (Regional Groundwater Hydrology). Previous analyses have determined that this area would not be subject to seawater intrusion, because the Serra Fault presents an effective barrier to seawater intrusion (Kennedy/Jenks 2012c).

Groundwater Elevations and Exclusion Heads

Average modeled groundwater levels were compared to the average groundwater levels predicted to occur under modeled existing conditions in order to determine the effect of Project-related pumping on the potential for seawater intrusion to occur. Average groundwater levels were used because short-term movement of the seawater interface towards land during periods of low groundwater can be offset by movement of the seawater interface towards the ocean during periods of high groundwater. Average groundwater elevations are appropriate because they address both the magnitude and duration of short term seawater intrusion.

If predicted average groundwater levels with the Project are lower than predicted average groundwater levels under modeled existing conditions, the groundwater levels are further compared to the exclusion head. Groundwater levels higher than the exclusion head indicate that seawater intrusion would not likely reach that well location. Groundwater levels lower than the exclusion head do not necessarily indicate that seawater intrusion would occur, but rather that the hydrologic potential exists for the

[25] The theoretical groundwater level that must be maintained at a well location to prevent seawater intrusion from reaching the well.

landward migration of the seawater-freshwater interface. Generally, however, seawater intrusion would occur eventually if groundwater levels remain lower than the exclusion head indefinitely, unless there are other factors, such as physical barriers, that control seawater intrusion (Kennedy/Jenks 2012c).

Seawater intrusion is not likely to occur due to seasonal fluctuation of groundwater levels, because seasonal fluctuations are temporary, and seasonal decreases are compensated for by seasonal increases (Kennedy/Jenks 2012c). Seasonal fluctuations may result in a wider seawater/fresh water transition zone, as mentioned above. This wider transition zone may result in elevated chloride concentrations near the coast. However, such a wider transition zone is not an indicator of ongoing seawater intrusion.

Groundwater Flux

The flux of groundwater moving towards the ocean or bay represents the amount of water discharging from the aquifer. The flux values are representative of the groundwater basin as a whole and indicate total discharge along the coast; this means that localized changes in flux that could allow localized seawater intrusion to occur would not be identified in this analysis. However, calculating flux values provides a gross evaluation of the amount of water discharging from the aquifer. A positive flux indicates a lower potential for seawater intrusion to occur, although a positive flux value does not necessarily preclude seawater intrusion from occurring because the seawater wedge could still enter the lowest part of the freshwater aquifer. Rather, the calculated flux is used as an indication of whether seawater intrusion is expected to be a substantial concern.

Groundwater Contours

Groundwater contours were used to evaluate groundwater elevations and flow directions in the shallow water bearing zone and Shallow Aquifer throughout the basin. In general, groundwater levels estimated to be above sea level and groundwater flow directions estimated to be directed toward the ocean or bay indicate that there is a low potential for seawater intrusion to occur.

Significance Threshold

As previously discussed, the recommended secondary MCL for chloride is 250 mg/L and the upper limit is 500 mg/L. An increase in chloride concentrations above these concentrations could render at least part of the groundwater basin unsuitable for use as a drinking water source. Therefore, this analysis considers that impacts related to seawater intrusion would be significant if chloride concentrations exceeded 250 mg/L at one of the monitoring locations along the Pacific Coast or San Francisco Bay.

Impact Discussion and Significance Determination

Potential for Seawater Intrusion in the North Westside Groundwater Basin

<u>Shallow Aquifer</u>

The results from the Westside Basin Groundwater Model predict that, in the North Westside Groundwater Basin, average groundwater levels in the Shallow Aquifer due to the Project would be equal to or higher than the average groundwater levels without the Project, that is, under modeled existing conditions (Kennedy/Jenks 2012c). As a result of the higher future groundwater levels that would accumulate through operation of the Project, seawater intrusion would tend to be impeded or prevented. The average rise in groundwater levels in the Shallow Aquifer, modeled at monitoring well clusters in the Basin, would be between 0 and 1.6 feet. The Model results predict that the Project's average groundwater levels would never be below the exclusion head for the Shallow Aquifer.

The average groundwater flux from the Westside Groundwater Basin to the Pacific Ocean is predicted to be 17 af per month (afm) higher under Project conditions than under modeled existing conditions. This increased flux would tend to either push the seawater wedge further seaward and west of the coast or allow less seawater intrusion into the Westside Groundwater Basin, although a positive flux value does not necessarily preclude seawater intrusion from occurring because the seawater wedge could still enter the lowest part of the freshwater aquifer. Although these increased flux estimates are not specific to the Shallow Aquifer, they do suggest that, generally, more groundwater flows towards the Ocean under Project conditions than under modeled existing conditions.

Groundwater contours for the Shallow Aquifer under Project conditions are predicted to be almost identical to groundwater contours for the Shallow Aquifer under modeled existing conditions (Kennedy/Jenks 2012c), except that during the design drought, groundwater levels south of Lake Merced are predicted to be up to 5 feet lower with the Project than without the Project. These predicted lower groundwater levels, however, represent conditions after the design drought and do not represent average conditions. Any seawater intrusion induced during the design drought would be pushed back out by the average groundwater levels associated with operation of the Project, which are predicted to be higher than those predicted under modeled existing conditions. Therefore, the Project would not cause lower groundwater levels that would induce seawater intrusion in the Shallow Aquifer of the North Westside Groundwater Basin.

<u>Primary Production and Deep Aquifers</u>

The results from the Westside Basin Groundwater Model predict that, in the North Westside Groundwater Basin, average groundwater levels with implementation of the proposed Project in the Primary Production and Deep Aquifers would be equal to or higher than the average groundwater levels without the Project. Average groundwater levels would be higher because they would rise during the Put Years during Project operations, and would remain high during the Hold Years. Only during Take Years would groundwater levels drop below the groundwater levels for the modeled existing conditions. The average rise in groundwater levels in the Primary Production Aquifer, estimated at monitoring well clusters in the North Westside Groundwater Basin, is expected to be between 0.1 and 3.3 feet. The average rise in groundwater levels in the Deep Aquifer, estimated at monitoring well clusters in the North Westside Groundwater Basin, is expected to be between 0.2 and 1.5 feet. These higher groundwater levels would impede seawater intrusion.

The Model results predict that the Project's groundwater levels in the Primary Production Aquifer would be below the exclusion head between 99 and 100 percent of the hydrologic sequence, taking into account the values at different locations. This is identical to the percent of time that groundwater levels in the Primary Production Aquifer are estimated to be below the exclusion head under modeled existing conditions. Therefore, the Project would not be expected to cause groundwater levels to be below the exclusion head more frequently than they would be under the modeled existing conditions.

The Westside Basin Groundwater Model results predict that the Project's groundwater levels in the Deep Aquifer would be below the exclusion head during 100 percent of the hydrologic sequence, which is the same as is expected to occur without the Project (i.e., modeled existing conditions).

Therefore, the Project would not induce seawater intrusion in the Primary Production or Deep Aquifers of the North Westside Groundwater Basin that is not anticipated under modeled existing conditions.

Impact Conclusion: Less than Significant

Potential for Seawater Intrusion in the South Westside Groundwater Basin

Shallow Water-bearing Zone

The results from the Westside Basin Groundwater Model predict that, under the proposed Project, simulated groundwater elevations in the South Westside Groundwater Basin would range between 0.2 feet below and 3.1 feet above modeled existing conditions. The average groundwater levels in the South Westside Groundwater Basin's shallow water bearing zone over the 47-year hydrologic modeling sequence due to the proposed Project are predicted to be equal to or higher than the average groundwater levels without the Project. These higher groundwater levels under the proposed Project would tend to impede seawater intrusion. The average rise in groundwater levels in the shallow water bearing zone groundwater levels, estimated at monitoring well clusters in the South Westside Groundwater Basin, is predicted to be between 0.8 and 2.0 feet over this time period.

The Westside Basin Groundwater Model results predict that the Project's groundwater levels in the shallow water bearing zone would be below the exclusion head during seven to 100 percent of the 47-year hydrologic sequence, taking into account multiple locations throughout the South Westside Groundwater Basin. Groundwater levels in the shallow water bearing zone would be below the exclusion head 10 to 100 percent of the time at those same locations under modeled existing conditions (i.e., without the Project). Therefore, the Project would not cause groundwater levels to be below the exclusion head more frequently than they would be under the modeled existing conditions.

Groundwater flux from the South Westside Groundwater Basin to the San Francisco Bay under Project conditions is predicted to range between 11 afm less to 8 afm more than what is predicted under modeled existing conditions. The average groundwater flux from the Westside Groundwater Basin to the San Francisco Bay is predicted to be 3 afm higher with the Project than without the Project. This increased flux would tend to either push seawater further towards San Francisco Bay or allow less seawater intrusion into the Westside Groundwater Basin. Although these increased flux estimates are not specific to the shallow water bearing zone, they do suggest that, generally, more groundwater would flow towards the Bay under Project conditions than under modeled existing conditions.

Therefore, the Project would not cause lower groundwater levels as compared to modeled existing conditions, such that seawater intrusion would be induced to a greater degree in the shallow water bearing zone of the South Westside Groundwater Basin.

Primary Production and Deep Aquifers

At the Burlingame-D monitoring well (located adjacent to San Francisco Bay in the South Westside Groundwater Basin Primary Production Aquifer), the Westside Basin Groundwater Model results predict that average groundwater levels with the proposed Project would be 1.3 feet higher than the average groundwater levels without the Project (Kennedy/Jenks 2012c). These higher groundwater levels would impede seawater intrusion.

The Westside Basin Groundwater Model results also predict that groundwater levels in the Primary Production Aquifer, measured at Burlingame-D monitoring well, would be below the exclusion head 100 percent of the hydrologic sequence under Project conditions. This is identical to the percent of time that groundwater levels in the Primary Production Aquifer are predicted to be below the exclusion head under modeled existing conditions. Therefore, the Project would not cause groundwater levels to be below the exclusion head more frequently than they would be under the modeled existing conditions.

Simulated groundwater elevations for the South Westside Basin Deep Aquifer are not readily available from the memoranda detailing the results of the Westside Basin Groundwater Model. However, the sediments present in the Deep Aquifer are not continuous to the Bay, being separated from it by deposits of low-permeability Bay Mud that likely stretch from the land surface to the bedrock surface below (Kennedy/Jenks 2012c). Therefore, any Deep Aquifer seawater intrusion would need to pass through the shallow water bearing zone and Primary Production Aquifer before reaching the Deep Aquifer. As discussed above, the Project would not induce seawater intrusion into either the shallow water bearing zone or Primary Production Aquifer. Therefore, given the lack of hydrologic connection between the Deep Aquifer and the bay, the Project would not induce seawater intrusion into the Deep Aquifer.

In summary, the Project would not cause lower groundwater levels that would induce seawater intrusion in either the North or South Westside Groundwater Basin; therefore, the potential impact on groundwater relative to seawater intrusion would be *less than significant*.

Impact Conclusion: Less than Significant

Impact HY-9: Project operation could have a substantial, adverse effect on water quality that could affect the beneficial uses of Lake Merced. (Less than Significant with Mitigation)

Description of Groundwater/Surface Water Interactions

The Project has the potential to affect Lake Merced due to groundwater/surface water interactions. The phrase "groundwater/surface water interactions" refers to the movement of water beneath the land surface (groundwater) to or from water bodies on the ground surface, such as streams, lakes, and wetlands (surface water). Several general conditions are required for groundwater/surface water interactions to occur. First, the depth to groundwater (the water table) has to be sufficiently shallow in relation to the bottom of the surface water body. While the water table does not have to connect with the surface water for interactions to occur, there cannot be a substantial distance between the two, and separations of tens or hundreds of feet would generally preclude groundwater/surface water interactions. There must also be a relatively permeable pathway (such as a sandy lakebed) between the groundwater and surface water for interactions to occur.

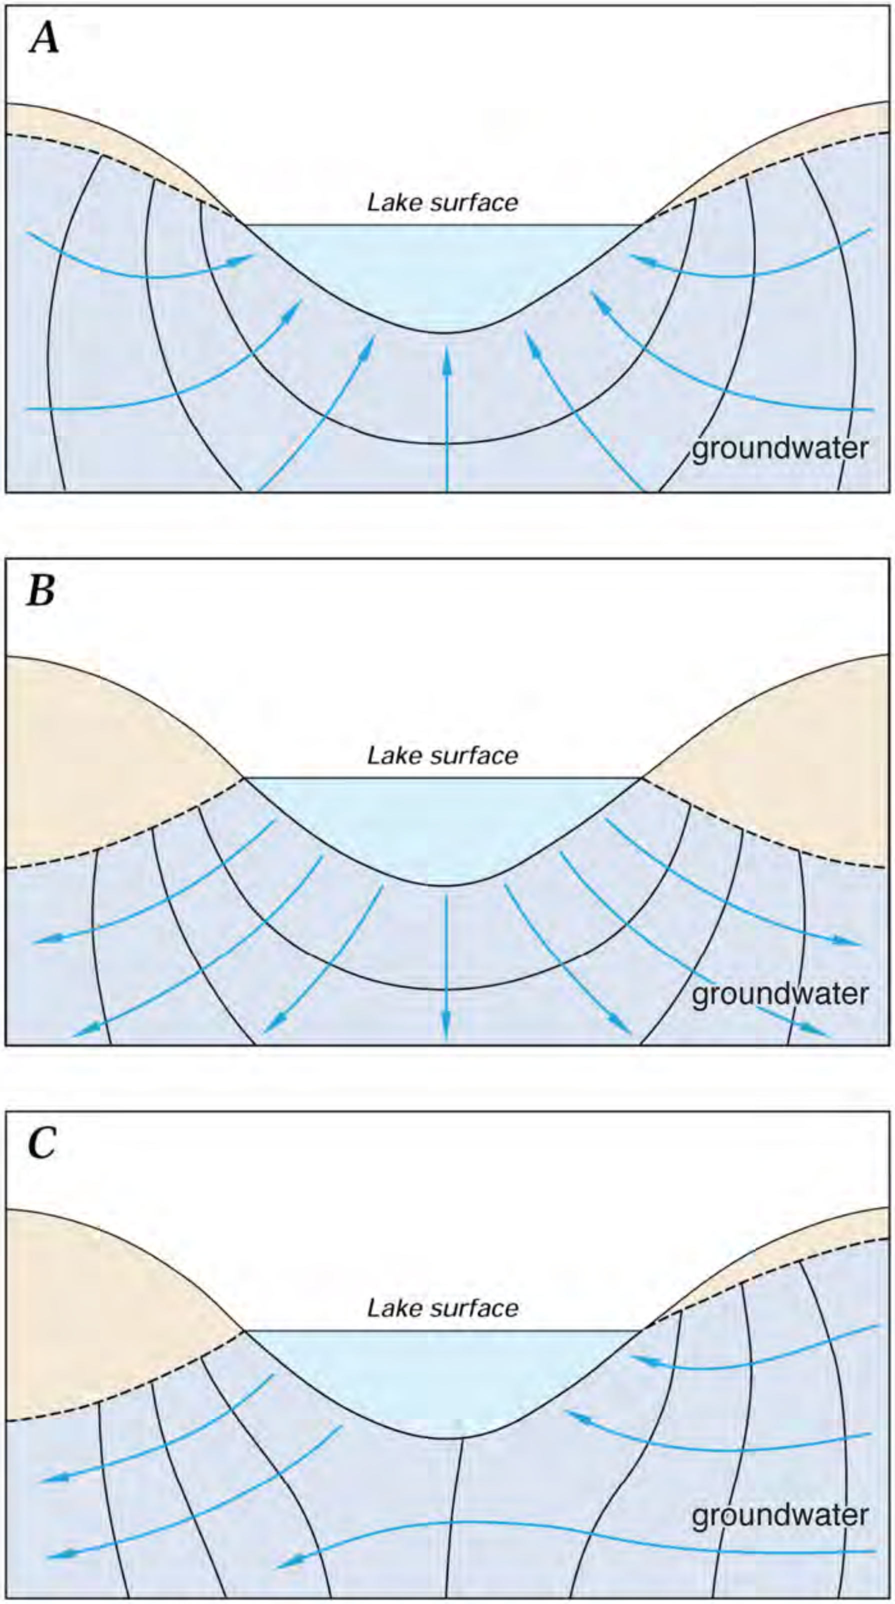
The presence of a clay layer or other low-permeability layer could preclude groundwater/surface water interactions, even if the water table were sufficiently shallow to otherwise allow interactions. Even with a natural sand lakebed, the settling of silt and organic-rich sediments from the lake water could reduce the permeability of the lake bottom, often restricting groundwater/surface water interactions to the areas along the sides of the lake where fine sediments would not have accumulated.

Surface water bodies such as lakes and streams can interact with groundwater in three basic ways (Kennedy/Jenks 2012d). They can gain water from the inflow of groundwater through the lakebed or streambed when the groundwater level is higher than the water level in the surface water body; this is referred to as a gaining system (illustration "A" on Figure 5.16-10 [Interaction of Groundwater and Lakes]). Surface water bodies can also lose water to the groundwater through the lakebed or streambed when the groundwater level is lower than the water level in the surface water body; this is referred to as a losing system (illustration "B" on Figure 5.16-10). In many cases, surface water bodies can both gain and lose water (e.g., during different seasons of the year), depending on the relative elevations of the groundwater table, the water level in the surface water body, as well as the groundwater flow direction in the aquifer (illustration "C" on Figure 5.16-10). The seepage rate between the lakebed or streambed and groundwater system is controlled by the permeability of the subsurface geology and the characteristics of the lakebed or streambed. In both gaining and losing systems, surface water levels can be affected by changes in groundwater elevations. Where the groundwater and surface water systems are disconnected, changes in groundwater elevations would not affect surface water levels.

To evaluate the potential for adverse effects on surface water bodies, it is important to understand changes in groundwater levels and related changes in surface water levels, as well as potential water quality effects related to changes in surface water levels. In general, a decrease in surface water levels would not be substantial unless the beneficial uses of the surface water were adversely affected.

Approach to Analysis

This impact analysis evaluates whether the proposed Project would result in significant changes in water quality due to changes in lake levels, which could in turn affect the beneficial uses of Lake Merced. This analysis is based on understanding the relationship of lake levels to water quality. It describes Lake Merced water levels predicted under the modeled existing conditions and then compares those levels with the projected lake water levels that are predicted to occur with implementation of the Project. Then, based on the magnitude, frequency, and duration of predicted changes in lake levels resulting from the Project, the analysis identifies the potential for water quality impacts that could affect beneficial uses.



Lakes can receive groundwater inflow (A), lose water as seepage to groundwater (B), or both (C). From Winter et al. (1998).

Interaction of Groundwater and Lakes

Regional Groundwater Storage and Recovery Project

Figure 5.16-10

Source: Kennedy/Jenks 2012 TM 10.2

This page left intentionally blank

As discussed above in Section 5.16.1.4 (Groundwater-Surface Water Interactions), under the sub-heading "Lake Merced Water Quality", the relationship between water quality and lake levels varies, with no substantial correlations observed at lake levels between 0 and 7 feet City Datum, which is the range of lake levels observed between 1997 and 2009. Since 2003, Lake Merced has been maintained at a water surface elevation of at least 3 feet City Datum, and this level has increased to at least 5 feet City Datum since early 2006. At approximately 4 feet City Datum, all of the individual lakes are hydraulically connected, which is assumed to allow circulation between the four water bodies that comprise the lake, which would be expected to enhance water quality in the lake, as a result. Based on this, if Lake Merced water levels were to remain at or above 0 feet[26] City Datum (consistent with the water levels observed since 1997) under the Project, it can be expected that the current water quality conditions observed in the lake would continue. Therefore, increases in lake levels are not expected to cause water quality degradation.

Water quality monitoring between 1997 and 2009 indicates that water quality parameters in the lake have generally achieved the water quality objectives specified in the Basin Plan, with the exception of some occurrences of dissolved oxygen levels less than the warmwater habitat criterion of 5 mg/L during the summer and late fall in the deeper portions of the lake (Kennedy/Jenks 2010a). Based on a review of available water quality data, the water quality conditions of Lake Merced remained relatively constant from 1997 to 2009, with a slight improvement in lake clarity (secchi depth) during this period.

No historic data are available to determine whether lake levels below 0 feet would cause water quality degradation. Given this lack of historic data, if Project-related groundwater pumping (rather than hydrologic or other factors) were to result in lake levels below 0 feet City Datum, the potential for water quality impacts is unknown. As a conservative assumption, the approach to this analysis assumes that water quality impacts could occur when lake levels are below 0 feet City Datum, including changes in the pH and dissolved oxygen levels, the parameters that are responsible for the listing of Lake Merced as an impaired water body (see discussion in Section 5.16.1.4 [Groundwater-Surface Water Interactions], under the sub-heading "Lake Merced Water Quality"). For the purposes of this EIR, this would be considered a significant impact.

To evaluate changes in Lake Merced water levels, the Westside Basin Groundwater Model (Kennedy/Jenks 2012a) was used to estimate Project-related groundwater-level changes in the vicinity of Lake Merced and to derive the magnitude and direction of the flux of the groundwater/surface water interactions at Lake Merced. Because this model does not take into account the site-specific geometry of the lakebed, the simulation of Lake Merced surface water levels is not always accurate. Therefore, the output from the groundwater flow model was used as input to the Lake-level Model (a spreadsheet-based mass balance model calibrated to 70 years of historical water levels in Lake Merced) to provide a more accurate estimate of Lake Merced water levels in response to changes in groundwater levels and groundwater flux. Use of the Lake-level Model allows for changes in the surface area of Lake Merced as a function of lake level, a dynamic simulation of changes in lake volume, a more complete evaluation of

[26] At a lake level of 0 feet City Datum, the depth of Lake Merced would range from approximately 6 to 17 feet of water, depending on the location in the lake.

stormwater runoff, and an evaluation of flooding events resulting from overflows of the Vista Grande Drainage Canal.

The modeled groundwater elevations from the following four monitoring well clusters in the vicinity of Lake Merced (see Figure 5.16-11 [Simulated Lake Merced Level Changes]) were used for the analysis of changes in groundwater levels:

- LMMW-1, located along the west shore of South Lake;
- LMMW-2, located between North and South Lakes;
- LMMW-3, located adjacent to the west shore of Impound Lake; and
- LMMW-4, located north of North Lake.

Lake Merced Water Levels under Modeled Existing Conditions

Figure 5.16-12 (Simulated Lake Merced Levels Relative to Modeled Existing Conditions) shows the estimated Lake Merced water levels over the 47-year simulation period under modeled existing conditions. The modeled existing conditions respond directly to the assumed hydrologic sequence and existing groundwater practices described in Section 5.1, Overview, Section 5.1.6 (Groundwater Modeling Overview). Lake levels increase during years 1 to 4, which are years of above-average precipitation, followed by a decline in lake levels in years 4 through 16, which are years of a dry period, to a low of 1.5 feet City Datum during a dry period. From years 16 to 36, lake levels fluctuate with climatic conditions, but show an overall increasing trend to over 11 feet City Datum. The model also simulates the hypothetical design drought in years 36 to 44, during which the lake levels decline sharply to -0.8 feet, then recover to about 5 feet City Datum. Over the simulation period, the mean monthly lake level is 6.3 feet City Datum and the estimated mean annual range is 1.6 feet (see Figure 5.16-12). The mean monthly lake levels are below an elevation of 1 foot City Datum for four percent of the simulation period. (Kennedy/Jenks 2012d)

Under modeled existing conditions, estimated Shallow Aquifer groundwater levels in the nearby monitoring wells also indicate a response to climatic conditions, but groundwater levels in the Primary Production Aquifer show less variability than in the Shallow Aquifer. Characteristic of the Westside Groundwater Basin, the estimated groundwater levels are generally higher for locations to the north of Lake Merced and lower for locations to the south. This difference reflects the influence of existing groundwater pumping in the South Westside Groundwater Basin. For Lake Merced, this means that under modeled existing conditions, there could be a higher net outflow of lake water to groundwater from the South and Impound Lakes, while there could be more inflow of groundwater to the North and East Lakes. (Kennedy/Jenks 2012d)

The overall pattern of estimated flux (i.e., groundwater flow into or out of Lake Merced), indicates that under the modeled existing conditions, there is net inflow of groundwater to the lake during periods of higher precipitation and a net outflow of lake water to groundwater during dry periods when groundwater levels decline. (Kennedy/Jenks 2012d)

Effects of Project-related Pumping on Lake Merced Water Levels

Figure 5.16-11 (Simulated Lake Merced Level Changes) shows the estimated Lake Merced water levels over the 47-year simulation period under Project conditions. The effects of Project-related pumping would be observed in groundwater levels in both the Shallow and Primary Production aquifers. In the Shallow Aquifer, groundwater levels during Project operation, at the LMMW-3 location (to the south of Lake Merced), are predicted to be generally higher than is predicted to be the case without the Project, as indicated by the modeled existing conditions. However, following the design drought, groundwater levels at the LMMW-3 location are predicted to be about 2 feet lower with operation of the Project than they are predicted to be under the modeled existing conditions, and at LMMW-4 to the north they are predicted to be about 1 foot lower than they are predicted to be under the modeled existing conditions. Groundwater levels in the Shallow Aquifer, with operation of the Project, are estimated to recover in one to two years following the design drought. (Kennedy/Jenks 2012d)

In the Primary Production Aquifer, groundwater levels are also predicted be higher with operation of the Project than is predicted to be the case under modeled existing conditions throughout most of the 47 years of the modeled simulation. However, at the end of the design drought, the groundwater levels at LMMW-3 are predicted to be about 2 feet lower with operation of the Project than they are predicted to be under the modeled existing conditions. At LMMW-4 to the north, the Primary Production Aquifer groundwater levels are predicted to be about 2 feet lower with operation of the Project than they are predicted to be under the modeled existing conditions. Groundwater levels at this location in the Primary Production Aquifer, with operation of the Project, are estimated to partially recover to pre-design-drought levels in three to four years following the end of the design drought. (Kennedy/Jenks 2012d)

The Lake Merced lake levels under Project conditions are predicted to be similar to the modeled existing conditions for the first two years of the simulation, but are then predicted to rise rapidly from approximately 9 feet to approximately 11 feet by year 10, as a result of higher precipitation and concomitant higher groundwater levels in the Shallow Aquifer. During years 44 to the end of the simulation, after the design drought, lake levels under Project conditions are still predicted to be about 4 feet below what they are predicted to be under the modeled existing conditions at the end of the simulation. (Kennedy/Jenks 2012d)

Simulated Lake Merced Levels Relative to Modeled Existing Conditions

Regional Groundwater Storage and Recovery Project

Figure 5.16-12

Source: Kennedy/Jenks 2012d (TM 10.2)

The lowest predicted lake level with operation of the Project, which is expected at the end of the design drought, is approximately -2 feet City Datum (compared to approximately -1.5 feet City Datum under modeled existing conditions; i.e., without the Project), which would leave approximately 4 feet of water in Impound Lake and about 9 feet of water in East Lake. (Kennedy/Jenks 2012d)

The predicted mean monthly lake level with operation of the Project is 9.1 feet City Datum (compared to approximately 6.3 feet City Datum under modeled existing conditions). Lake levels with operation of the Project are predicted to be below 5 feet for 14 percent of the simulation period, whereas lake levels are predicted to be below 5 feet for 33 percent of the simulation period under the modeled existing conditions. Lake levels with operation of the Project are predicted to be below 1 foot for 10 percent of the simulation period, whereas lake levels are predicted to be below 1 foot for four percent of the simulation period under the modeled existing conditions. Overall, lake levels are predicted to be higher under the Project conditions than under the modeled existing conditions for approximately 90 percent of the time during the 47-year simulation, but lake levels are predicted to be lower than modeled existing conditions during and after the design drought for approximately 10 percent of the 47-year simulation. (Kennedy/Jenks 2012d)

Relative to the modeled existing conditions, the estimated outflow from Lake Merced to the groundwater under the proposed Project is predicted to be generally lower due to the higher groundwater levels associated with operation of the Project for most of the 47-year simulation period, although groundwater inflows to the lake are predicted to be reduced relative to the modeled existing conditions during and after the design drought. (Kennedy/Jenks 2012d)

Impact Discussion and Significance Determination

Although Lake Merced lake levels are predicted to be higher under the Project than under modeled existing conditions for approximately 90 percent of the time, as shown in Figure 5.16-12 (Simulated Lake Merced Levels Relative to Modeled Existing Conditions), Lake Merced water levels are also predicted to be lower than modeled existing conditions during and after the design drought. Following the design drought, water levels in Lake Merced are predicted to decrease due to the Project by about 4 feet more than under modeled existing conditions for at least three years. If water levels are reduced to this extent during and after the design drought, more of the lake bed would be exposed, making it susceptible to erosion and associated sedimentation of the lake, and the four individual lakes would separate hydraulically. Groundwater inflows to the lake are also predicted to be reduced relative to the modeled existing conditions during and after the design drought.

As described in Section 5.16.1 (Setting), Lake Merced is currently affected by periods of weak stratification and there have been episodes of low dissolved oxygen noted between 1997 and 2009. When the lake stratifies during the summer, dissolved oxygen levels are typically near saturation (approximately 10 mg/L) at the surface, with hypoxic (dissolved oxygen levels of less than 5 mg/L) or anoxic (dissolved oxygen levels of less than 2 mg/L) conditions in the bottom. The lake usually “turns over,” or mixes, in the fall and stays well-mixed throughout the winter. When the lake is mixed, dissolved oxygen levels are typically consistent throughout the entire water column, but these levels tend to be below saturation (approximately 8 mg/L, with a range of 6 to 10 mg/L). The lake is listed by the RWQCB as impaired for pH and dissolved oxygen.

Reduced lake levels and groundwater flows into the lake could also increase eutrophication of the lake because nutrients discharged to the lake would be concentrated in a smaller lake volume. Also, with a smaller volume, the lake would likely mix more frequently, and as a result (based on the patterns described above) this would likely increase dissolved oxygen levels at the bottom while decreasing dissolved oxygen levels at the surface. Therefore, depending on conditions, increased pumping under the proposed Project during Take Periods could increase the episodic occurrences of low dissolved oxygen and could also affect the pH of the lake water, potentially exacerbating the conditions that are responsible for the listing of Lake Merced as an impaired water body. Reduced groundwater inflows during and after Take Periods could affect nitrogen inflow to the lake from groundwater and also result in the increased concentration of suspended solids, metals, hydrogen sulfide, and bacteria already present in the lake, and less dilution of these constituents if they are discharged to the lake from stormwater flows.

As discussed in Section 5.16.2.1 (Federal and State Regulations) under the sub-heading "Regional Water Quality Control Board, Beneficial Uses," the Basin Plan identifies existing beneficial uses of Lake Merced as body contact recreation (e.g., fishing), noncontact recreation (e.g., picnicking, sightseeing, rowing), warm freshwater habitat, cold freshwater habitat, fish spawning, and wildlife habitat. Municipal and domestic supplies are also potential beneficial uses of Lake Merced. Adverse changes in water quality parameters such as dissolved oxygen and pH, as well as increased algal levels, could adversely affect the identified beneficial uses of Lake Merced that are related to warm freshwater habitat, cold freshwater habitat, and fish spawning, which, depending on the magnitude, duration, and frequency of such changes, could be considered a significant impact on water quality.

Because the Project is predicted to result in the lowering of Lake Merced water levels to below 0 feet City Datum somewhat more frequently than is predicted to occur under modeled existing conditions (from four percent of the 47-year simulation to 10 percent of the simulation), there is the potential for the Project to result in water quality changes that would compromise water quality objectives related to warm and cold freshwater habitat (e.g., dissolved oxygen), which in turn could adversely affect associated beneficial uses. Changes in dissolved oxygen levels and pH could also exacerbate conditions responsible for listing Lake Merced as an impaired water body during and after the design drought. This would be a *significant* impact on water quality.

Although municipal and domestic supplies are listed as potential beneficial uses of Lake Merced, the City and County of San Francisco (CCSF) has not used the lake as a municipal supply since the 1930s, as discussed in Section 5.16.1.4 (Groundwater-Surface Water Interactions) under the sub-heading "Existing Uses of Lake Merced." Further, as discussed below, the SFPUC would implement corrective action to ensure that long-term changes in water quality do not occur. Short-term changes in water quality associated with lowered lake levels would not be expected to affect the potential beneficial use of Lake Merced as a municipal supply because the need to rely on Lake Merced for the CCSF's water supply would occur only during a catastrophic emergency, and the City would direct residents to boil tap water prior to its consumption if such an unlikely emergency usage were to occur. (SFPUC 2012d)

Impacts related to water quality and associated beneficial uses of Lake Merced would be reduced to a *less-than-significant* level with implementation of Mitigation Measures M-HY-9a (Lake Level Monitoring and Modeling for Lake Merced) and M-HY-9b (Lake Level Management for Lake Merced). These measures require the SFPUC to implement lake level management procedures to maintain Lake Merced water levels above 0 feet City Datum. These procedures include the continuation of lake-level and groundwater monitoring; redistribution of pumping patterns or decreasing the Project pumping rate; or additions of supplemental water (either from the regional system water, treated stormwater, or recycled water), if available. Supplemental water would be supplied from the regional water system, dechlorinated, and introduced to Lake Merced at the existing Lake Merced pumping station, in the same manner that supplemental water has been added to Lake Merced several times in the past. However, in the event that surface water supplies were not available due to maintenance, drought, or a declared emergency resulting from an earthquake or other disaster, the SFPUC could add treated stormwater or recycled water, if available (SFPUC 2012f).

Implementation of these measures would ensure that any lake level declines to below 0 feet City Datum as a result of the Project would be avoided through redistribution of pumping patterns or decreasing the Project pumping rate, or potentially through the addition of supplemental water. Although redistribution of pumping and the addition of supplemental water may or may not be feasible and effective under all circumstances, a decrease in Project pumping would be feasible and effective at mitigating lake level declines below 0 feet City Datum in any case. As a result, the Project would not cause changes in water quality that would adversely affect the potential beneficial uses of Lake Merced and, therefore, would result in a *less-than-significant* impact on the water quality of Lake Merced.

Implementation of redistribution of Project pumping under Mitigation Measure M-HY-9b (Lake Level Management for Lake Merced) would not cause significant seawater intrusion or well interference impacts, because the SFPUC would be able to avoid such impacts through alteration or stopping redistribution of pumping as needed. (SFPUC 2012a)

The Project's effect on Lake Merced water levels could also affect the soil and sediments of Lake Merced near the former Pacific Rod and Gun Club on the western shore of South Lake. Lead and other metals as well as clay target fragments (including associated organic chemicals) have been identified in the soil and sediments in this area. However, the Project would not result in adverse water quality effects related to this site either due to increasing or decreasing Lake Merced lake levels. If the Project were to result in a decrease in Lake Merced water levels, it may expose portions of the lakebed to the air. However, these portions of the Lake Merced lakebed have been exposed in the past and subsequently refilled; water quality sampling of this portion of the lake indicates that no dissolved lead was detected after the lake refilled. Fluctuations of Lake Merced predicted to occur due to Project operations, including increases in lake levels, are similar to historic fluctuations that have occurred in Lake Merced. Even with these historic fluctuations, lead has not been found in the lake water, and, therefore, Project-related lake-level increases or decreases at Lake Merced are expected to have no impact on Lake Merced water quality relative to lead (SFPUC 2012g).

Mitigation Measure M-HY-9a: Lake Level Monitoring and Modeling for Lake Merced

The SFPUC shall implement lake level monitoring and modeling in accordance with the process described below. The SFPUC will conduct monitoring to detect changes in lake level and water quality, as well as groundwater-level elevations. Implementation of this measure shall be coordinated with the SFPUC's ongoing Lake Merced lake-level, water quality, and groundwater monitoring programs to document and maintain the database of these parameters throughout Project operations.

The SFPUC shall continue to maintain the Lake-level Model so as to be able to evaluate what lake levels may have been without implementation of the Project based on the actual hydrology that occurs during Project implementation. As described below, the SFPUC shall use the model to determine the amount of lake-level change that is attributable to the Project rather than to hydrologic or other factors.

Mitigation Measure M-HY-9b: Lake Level Management for Lake Merced

Prior to beginning operation of the Project, the SFPUC shall implement this lake level management program as follows:

- If lake levels are within the range that would occur without the Project based on maintenance of the Lake-level Model, no corrective action shall be required.
- If lake levels are below the range that would have occurred without the Project, corrective action shall be implemented in time to prevent lake levels from declining as a result of Project-related pumping below 0 feet City Datum or the level that would occur without the Project, whichever is lower. One or both of the following corrective actions shall be implemented:
  - Redistribute pumping to decrease Project pumping rates in the vicinity of Lake Merced or decrease the overall Project pumping rate. However, in no case would redistribution be undertaken where groundwater levels would decline more than from the Project as originally predicted by modeling.
  - Augment lake levels through the addition of supplemental water (such as potable water that is dechloraminated at the Lake Merced Pump Station, stormwater from the Vista Grande Drainage Canal, recycled water, or stormwater diverted from other development in the Lake Merced watershed), if available.

Impact Conclusion: Less than Significant with Mitigation

Impact HY-10: Project operation would not have a substantial adverse effect on water quality that could affect the beneficial uses of Pine Lake. (Less than Significant)

As discussed in Section 5.16.1 (Setting) Pine Lake is incised in the Shallow Aquifer and, therefore, lake levels are directly affected by changes in groundwater levels in the Shallow Aquifer. While there are no designated uses for Pine Lake per the Basin Plan, the water quality of the lake could be affected by lake level decreases, similar to what could occur at Lake Merced. Therefore, if the Project causes the lake level to drop below the existing level of 40.1 feet NGVD 29, then water quality in the lake could decline.

The Westside Groundwater Basin Model does not simulate Pine Lake levels, or the shallowest groundwater levels in the Shallow Aquifer. However, lake losses to the groundwater aquifer are directly proportional to changes in groundwater levels. Therefore, changes in Pine Lake water levels can be inferred from changes in groundwater levels in monitoring well LMMW-5S, located near Pine Lake and which monitors groundwater in the deeper portion of the Shallow Aquifer. (Kennedy/Jenks 2012d)

The Westside Basin Groundwater Model for the Project scenario predicts a general increase in groundwater levels at monitoring well LMMW-5S of up to several feet above those expected under modeled existing conditions, until near the very end of the simulation period, when there is a slight reduction after the design drought. The absence of any extended periods of reduced groundwater levels indicates that the Project would have little or no effect on groundwater levels near Pine Lake. Therefore, the lake would be maintained at levels similar to those that are predicted under the modeled existing conditions. As a result, the Project would not cause any significant changes to water quality or to the health of the lake.

In addition, the San Francisco Park and Recreation Department maintains Pine Lake's level by pumping from the Stern Grove well. Further, the Westside Basin Groundwater Model incorporates a sufficient amount of pumping (up to 0.013 mgd [15 afy]) to maintain Pine Lake at the elevation of 40.1 feet NGVD 29; maintenance of the lake at this level would not result in any changes to water quality or the health of the lake. Therefore, water quality impacts related to potential adverse effects on Pine Lake water levels would be *less than significant*.

Impact Conclusion: Less than Significant

Impact HY-11: Project operation would not have a substantial adverse effect on water quality that could affect the beneficial uses of Colma Creek, San Bruno Creek, Lomita Channel, or Millbrae Creek. (Less than Significant)

The Westside Basin Groundwater Model predicts that the average annual groundwater outflow to the three creeks together would increase from 94 afy under modeled existing conditions to 122 afy with the Project (Kennedy/Jenks 2012d). Based on these results from the model, which predict little effect on the creeks, and because of the limited hydrogeologic connection between the creeks and groundwater, it is unlikely that groundwater-surface water interaction processes are present to any measureable extent for Colma, San Bruno, or Millbrae creeks. The Lomita Channel is an improved earth channel with a small (0.65 square mile) drainage area. The existing groundwater level in the vicinity of the Lomita Channel is approximately 20 feet below ground surface and is not expected to increase as a result of the Project (Kennedy/Jenks 2012d). As a result, no effect on the exchange between surface water and shallow groundwater at the Lomita Channel is expected. Therefore, the impact of the Project on Colma, San Bruno, and Millbrae creeks, and the Lomita Channel relative to potential groundwater-surface water interactions would be *less than significant*.

Impact Conclusion: Less than Significant

Impact HY-12: Project operation would not cause a violation of water quality standards due to mobilization of contaminants in groundwater from changing groundwater levels in the Westside Groundwater Basin. (Less than Significant)

Description of Water Quality Impacts

Operation of the Project could violate water quality standards or waste discharge requirements in two ways: 1) if the groundwater pumped as part of the Project, after proposed treatment and/or blending as described in Chapter 3, Project Description, would not meet drinking water standards; or 2) if Project operation would change groundwater levels or change groundwater flow patterns such that areas of existing contamination could be mobilized or spread in groundwater, or existing remediation activities could become substantially less effective.

Approach to Analysis

Groundwater Pumped by Project May Violate Drinking Water Standards

To determine whether groundwater pumped by the Project would meet drinking water standards, preliminary Drinking Water Source Assessment and Protection Program (DWSAP) reports have been prepared by the SFPUC for the wells proposed at Sites 1 through 16. Refer to Section 5.16.2 (Regulatory Framework) for a description of the DWSAP Program. Preliminary DWSAP reports have not been prepared for the proposed alternate sites at Site 17 (Alternate), 18 (Alternate), and 19 (Alternate); if wells at these alternate sites were selected for construction, DWSAP reports would be required. For the analysis, the information in the preliminary DWSAP reports for Sites 8, 10, and 12 are used to characterize the vulnerability of Sites 17 (Alternate), 18 (Alternate), and 19 (Alternate), respectively, because the close proximity of the referenced sites means that water quality parameters would likely be substantially similar.

The preliminary DWSAP reports approximate the size of the Groundwater Protection Zones for the wells representing the overlying areas where groundwater may be drawn into the well during two, five, and ten years of pumping. They also report on the degree that the wells would be protected from contamination based on the local hydrogeology and construction features (physical barrier effectiveness) and identify possible contaminating activities (PCAs) within the Groundwater Protection Zones established for the wells. Examples of PCAs are known contaminant plumes, leaking underground storage tanks, dry cleaners, and gas stations. Each PCA is assigned a risk score correlated to the potential for that PCA to contaminate groundwater, with the risk score being based on the land use type of the PCA, which Groundwater Protection Zone the PCA is located in, and the effectiveness of local hydrogeology and well construction methods to prevent potential contamination in groundwater from entering the well. The combined vulnerability score for a PCA can range from 3 to 17 points, and the CDPH considers water supply wells to be vulnerable to PCAs with a score of 8 or higher.

For this analysis, a Groundwater Protection Zone with a radius 2,000 feet was assigned for each SFPUC Project well and each Partner Agency well. This radius is greater than the 1,500 to 1,900 feet approximated by the preliminary DWSAP reports for Groundwater Protection Zones for ten years of pumping. PCAs within 2,000 feet of SFPUC Project wells and Partner Agency wells are identified as potential sources of contamination to the production wells. The likelihood of contamination migrating from the PCAs at or near the surface to the production wells is evaluated based on an assessment of vertical flow from the shallow groundwater zone to the Primary Production Aquifer that supplies the Project and Partner Agency wells.

Groundwater contamination that is not associated with specific PCAs is also identified and the likelihood of this contamination resulting in groundwater from production wells exceeding drinking water standards is evaluated based on modeled changes in groundwater contours due to the Project.

Any violation of drinking water standards at production wells resulting from Project operation would be addressed by proposed treatment and/or blending as described in Chapter 3, Project Description, Section 3.4.2.2 (Well Facility Types).

Project Operations May Mobilize or Spread Contamination in Groundwater or Cause Remediation Systems to Become Less Effective

To determine whether Project operations could mobilize or spread existing contamination in groundwater or cause remediation systems to become less effective, the analysis examines the extent to which the Project could increase shallow groundwater zone levels and change shallow groundwater zone flow directions. Areas where existing groundwater levels are predicted to be below a depth of 70 feet under modeled existing conditions are evaluated differently from areas where existing groundwater levels are above a depth of 70 feet. A depth of 70 feet is selected because contamination at PCAs is assumed to be limited to the top 50 feet below ground surface; the additional 20 feet serves as a buffer between the shallow groundwater zone level and contamination at the PCA to prevent mobilization of existing contaminants. (Kennedy/Jenks 2012e, SFPUC 2013b)

PCAs do not include nitrate contamination that occurs sporadically in the Westside Groundwater Basin at various depths. A discussion of nitrate contamination is included in the evaluation of Project impacts relative to drinking water standards.

Where existing groundwater levels are below a depth of 70 feet under modeled existing conditions, and groundwater levels are predicted to rise above a depth of 70 feet due to Project operations, PCA contamination could be mobilized or spread in groundwater. These groundwater level rises could potentially mobilize contaminants beyond the downward migration that could occur with recharge under modeled existing conditions. When groundwater levels are not predicted to increase to within 70 feet or are predicted to decrease, it is presumed that shallow contamination would not be mobilized and spread by the Project.

Where existing groundwater levels are above a depth of 70 feet under modeled existing conditions, it is assumed that PCA contamination is already mobilized and could spread in the shallow groundwater zone (unless there is an active remediation system). If groundwater levels increase enough due to the Project to saturate an area of contamination that is undergoing remediation with, for example, a vapor recovery program dependent upon unsaturated soils, then the effectiveness of the remediation efforts could be adversely affected. Likewise, changes in shallow groundwater zone flow directions due to the Project could adversely affect pump-and-treat remediation systems that would have been designed for flow directions assumed under modeled existing conditions. If predicted groundwater levels do not increase enough or predicted groundwater zone flow directions do not change substantially to adversely affect remediation systems under the Project, it is presumed that shallow contamination would not be mobilized by the Project.

<u>Physical Processes Affecting Water Quality in the South Westside Groundwater Basin</u>

South Westside Groundwater Basin geology and the related aquifer system are described in detail in Section 5.16.1.3 (Regional Groundwater Hydrology). The primary physical processes affecting water quality in the South Westside Groundwater Basin consist of 1) groundwater recharge and groundwater gradients, and 2) contaminant fate and transport processes.

Some components of groundwater recharge can transport contaminants from the surface to the underlying regional aquifer system. The primary sources of groundwater recharge are vertical percolation of rainfall, applied irrigation water, subsurface inflow from surrounding areas and leakage from water supply and sewer pipes (HydroFocus 2011). Horizontal and vertical groundwater gradients can transport contaminants laterally between areas and downward to the underlying aquifer systems assuming there is a hydraulic connection. Groundwater gradients are a function of the difference in groundwater elevations within the same groundwater zone (horizontal gradient) or between different groundwater zones or aquifers if there is a direct hydraulic connection (vertical gradient). Larger differences in groundwater elevations result in steeper gradients which in turn can accelerate groundwater flow. On the other hand, smaller differences in groundwater elevations result in shallower gradients which in turn can slow groundwater flow. The ability for contaminants to affect water quality is largely controlled by the chemical properties of the contaminants (e.g., solubility, vapor pressure, soil retardation density, and stability).

The Primary Production Aquifer is generally disconnected hydraulically from most occurrences of shallow groundwater zones in the bulk of the South Westside Groundwater Basin by an unsaturated zone and in most places by the presence of shallow fine-grained materials. The aggregate thickness of the fine-grained materials that make up discontinuous low permeability zones reduces the possibility for vertical migration of contaminants between the shallow groundwater zone and Primary Production Aquifer. These relatively low-permeability shallow sediments in the area from Daly City to South San Francisco are markedly different than the higher-permeability shallow sands found in the North Westside Groundwater Basin. (Kennedy/Jenks 2012e)

Even though permeability is reduced, the shallow water-bearing zone and Primary Production Aquifer have limited hydraulic connectivity, and the GSR Project would therefore affect downward gradients and flow. The downward gradient with the GSR Project would be smaller on average because the time-averaged water levels in the Primary Production Aquifer would be higher (Kennedy/Jenks 2012a). Consequently, the downward movement of contaminated groundwater from the shallow water-bearing zone would generally be less than under existing conditions. The vertical permeability of the sediments between the two zones is low, which means that downward movement of groundwater and contaminants is expected to be relatively slow. This low rate of movement would provide more time to detect and remediate contamination from surface sources before it reaches the Primary Production Aquifer.

At a number of PCA sites, groundwater is encountered at depths more shallow than groundwater levels in the shallow groundwater zones. These groundwater occurrences represent localized perched groundwater that is not hydraulically connected with the shallow groundwater zone. When there is no hydraulic connection, the migration of contaminants from the localized perched groundwater or the soils above the localized perched groundwater to the shallow groundwater zone is limited by recharge rates.

Known Areas of Contamination

An inventory of existing PCAs, such as known contaminant plumes, leaking underground storage tanks, dry cleaners, and gas stations, was compiled and evaluated as part of preliminary DWSAP reports prepared for the proposed wells at Sites 1 through 16. In addition, records of known PCAs within a 2,000-foot radius of wells proposed at Sites 1 through 16 were compiled from the following sources (Kennedy/Jenks 2012e):

- Known contaminating activities from GeoTracker;
- Known historical land disposal sites;
- Records of DTSC sites; and
- Records of SLIC sites (Spills, Leaks, Investigations, and Cleanup).

In addition, environmental cases and spill sites located within 0.25 mile of proposed well facility sites are summarized in Table 5.17-1 (Hazardous Materials Release Sites Identified within 0.25 Mile of a Facility Site Construction Area) in Section 5.17, Hazards and Hazardous Materials.

A total of 153 PCAs were identified within the 2,000-foot-radius zones surrounding the proposed well sites. Of the 153 PCAs, 51 were reported to be open, and the remaining 102 were reported closed under regulatory oversight. The PCA sites that are reported to be closed under regulatory oversight are not anticipated to pose a groundwater quality risk given that cleanup at these sites has been completed and residual contamination, if any, is assumed to be low. Among the 51 PCAs reported to be open, several are reported to have affected soil only with no groundwater contamination, and the majority of the remaining sites are related to shallow groundwater contamination underlain by low permeability fine-grained materials. Contaminants at these sites occur at the surface and tend to remain near the surface due to the chemical properties of the contaminants and the geologic conditions that slow the migration of these contaminants into the deeper underlying Primary production Aquifer. Contaminants can occur in soil above shallow groundwater encountered at the site or in the groundwater encountered at the site. The shallow groundwater encountered at the site may be localized perched groundwater or part of a larger shallow groundwater zone. The encountered depth to water at each PCA site is an estimate of the maximum depth of soil contamination or the depth of contamination in perched groundwater, if applicable. The reported depths to water were shallower than 50 feet below ground surface in nearly all the active and inactive regulated sites. The one exception that has been identified is the Arco#465 site where groundwater was encountered 56 feet below ground surface; this site is discussed specifically below. (Kennedy/Jenks May 2012e)

Only two of the 51 open PCAs within the 2,000-foot radius zones surrounding the proposed GSR well sites were characterized in the SWRCB's GeoTracker database system as potentially affecting aquifer media used for drinking water supply (Kennedy/Jenks May 2012b). These two PCAs, discussed below, are located in proximity to Sites 2, 3, and 4. One additional PCA, which was not identified as potentially affecting a drinking water aquifer, is also described below due to its proximity to the proposed well at Site 16. A fourth PCA was identified as having an active remediation system and is within the 2,000-foot radius of the San Bruno #17 production well. The remaining PCAs with contaminated soil and/or shallow water-bearing zones are not summarized in detail below given the shallow nature of the contamination at the sites and the hydraulic separation provided by the aggregate thicknesses of intervening clay and sand layers. For additional information about these sites, refer to Table 5.17-1 (Hazardous Materials Release Sites Identified within 0.25 Mile of a Facility Site Construction Area) in Section 5.17, Hazards and Hazardous Materials.

Arco #0465 (T0608100027) – Located within 2,000 feet of Sites 2, 3 and 4

This PCA is listed as an active ARCO gasoline station with underlying soil and shallow groundwater affected with petroleum hydrocarbons. This site is located on the southern corner of the intersection of Southgate Avenue and Lake Merced Boulevard in Daly City, about 700 feet northeast of the existing Daly City Westlake production well and about 1,000 feet northwest of Sites 2, 3, and 4. Based on the 2009 monitoring report available at the GeoTracker website, on-site monitoring wells were screened from 39 to 70 feet below ground surface. Data available at the GeoTracker website indicate a shallow depth to groundwater at approximately 56 feet below ground surface, based on data measured in 2002. (Kennedy/Jenks 2012e)

A deep on-site monitoring well installed to a depth of 220 feet below ground surface (below an approximate 10-foot-thick clayey silt to silt clay zone) observes groundwater levels at much lower depths (approximately 154 feet below ground surface), which may represent the intermediate regional drinking water aquifer (i.e., Primary Production Aquifer). Groundwater sampling conducted in 2009 at the intermediate on-site monitoring well and off-site shallow monitoring well (screened from 39 to 49 feet below ground surface) detected no petroleum hydrocarbons. On-site shallow monitoring wells showed plume concentrations to be either stable or declining over time, with the contaminant plumes being contained on site. (Kennedy/Jenks 2012e)

Gas and Wash Partners (T10000003031) - Located within 2,000 feet of Sites 2, 3 and 4

This PCA is listed as a LUST cleanup site and is located approximately 1,900 feet east of Sites 2, 3, and 4, and about 470 feet north of Daly City Well No. 4. Contamination at this site was discovered in February 2011, when the current property owner conducted sampling beneath three underground storage tanks that were proposed to be converted to use for storage of recycled water. Sampling indicated a historical release of gasoline, benzene, toluene, and xylene from two of the three storage tanks and one of the fuel dispensers. Based on the particular contaminants encountered in the sampling, consultants for the site have speculated that the petroleum hydrocarbon release occurred before the introduction of oxygenated gasoline in the late 1970s to late 1980s; the fuel storage tanks were lined in early 1999. The investigation was limited to soil sampling and did not sample deeper than just below the USTs; groundwater was not encountered or sampled. The detected concentrations of petroleum hydrocarbons were above the Environmental Screening Levels (ESLs) mandated for shallow soil at a commercial property over a potential drinking water source. Consultants for the site noted that a nearby LUST site (approximately 500 feet to the east) had groundwater depths no shallower than 160 feet below the ground surface. Based on the current information available from the site investigation report, there is no supporting data indicating this site has affected the drinking water supply aquifer. (Kennedy/Jenks 2012e)

Olympic Service Station (T0608121993) - Located within 2,000 feet of Site 16

This PCA is listed as an existing service station located about 980 feet upgradient and west of Site 16. During the course of aquifer tests at the Project monitoring well at Site 16, the water level in a shallow monitoring well (Olympian MW-3, located at the Olympic Service Station) about 950 feet west of Site 16 was monitored. This was done to determine whether the pumping at Site 16 would affect any surrounding wells in the shallow groundwater zone. The pumping at Site 16 resulted in no discernible effects on the groundwater levels at the Olympic Service Station monitoring wells. (Kennedy/Jenks 2012e)

Based on the review of the Pangea Environmental Services, Inc., 2008 Groundwater Monitoring Report (Pangea Environmental Services, Inc., 2008) available on the GeoTracker website, concentrations of total petroleum hydrocarbons as gasoline (TPHg) and benzene detected in on-site monitoring wells are on long-term declining trends, while total petroleum hydrocarbons as diesel (TPHd) have been generally stable. No methyl tert-butyl ether (MTBE) was detected in the easternmost downgradient monitoring well (MW-3), which is the closest well, at a distance of 950 feet from Site 16. Soil sampling indicates that MTBE attenuated to a concentration of approximately 0.88 parts per billion (ppb). (Kennedy/Jenks 2012e)

The compounds detected at the Olympic Service Station site appear restricted to the shallow groundwater zones, based on data from the well log for Site 16. This is supported by depth to water data available at the GeoTracker website indicating shallow depth to groundwater conditions at approximately 17.5 feet below ground surface, based on data measured in 2003. The shallow groundwater zone is underlain by clay/Bay Deposits from about 100 feet to 170 feet below ground surface. (Kennedy/Jenks 2012e)

Chevron 9-5584 (T0608179897) – Located within 2,000 feet of San Bruno #17

This was a former Chevron station. Currently, a strip mall and parking lot occupy the site. It is located on the northeastern corner of the intersection of El Camino Real and San Benito Avenue, about 1,700 feet south of the existing San Bruno production well No.17. Site monitoring data indicate shallow depth to water, with water levels ranging from about 20 feet to 60 feet below ground surface. This is consistent with data available at the GeoTracker website indicating a shallow depth to water table at approximately 34 feet below ground surface, based on data measured in 2003, as reported by the GeoTracker records. The site has both soil vapor and groundwater extraction wells. The most recent monitoring event in March 2010 shows a benzene and TPH plume mostly contained on site. (Kennedy/Jenks 2012e)

As discussed under the "Groundwater Quality" sub-heading in Section 5.16.1.3 (Regional Groundwater Hydrology), isolated occurrences of elevated nitrate concentrations in groundwater above the primary drinking water MCL of 45 mg/L occur in portions of Daly City and South San Francisco. These include occurrences in the Primary Production Aquifer. Also discussed is the potential presence of VOCs in the Primary Production and Deep Aquifer monitoring wells at Site 1 in Daly City and Site 11 in South San Francisco.

Impact Discussion and Significance Determination

Groundwater Pumped by Project May Violate Drinking Water Standards

The results of the preliminary DWSAP reports for each proposed Project well identified PCAs within Groundwater Protection Zones resulting in vulnerability scores of 8 and higher (Kennedy/Jenks 2009a through 2009g, 2010a through 2010k). As noted in Section 5.16.3.3 (Approach to Analysis of Operational

Impacts), these scores indicate that groundwater near these wells may be vulnerable to contamination from nearby land use activities. The types of PCAs identified in the Groundwater Protection Zones around the proposed wells are reflective of activities found in most urban settings, such as automobile gas stations, leaking underground tank sites, chemical/petroleum processing, sewer collection systems, and transportation corridors.

The proposed wells would extract water from the Primary Production Aquifer, in general from 340 feet to 700 feet below ground surface, except at Site 16 where the proposed screen would be from 240 feet to 410 feet below ground surface (Kennedy/Jenks 2012e). The Partner Agency production wells also extract water from the Primary Production Aquifer. As described in the Approach to Analysis above, under the sub-heading "Known Areas of Contamination," the PCAs identified within the delineated 2,000-foot radius Groundwater Protection Zones surrounding the SFPUC and Partner Agency well sites have been detected in soil only or in shallow groundwater on the order of 30 to 50 feet below ground surface (Kennedy/Jenks 2012e). As concluded in the preliminary DWSAP reports, because the proposed SFPUC wells would be drawing groundwater from the Primary Production Aquifer, the groundwater to be pumped is not considered to be particularly vulnerable to soil or groundwater contaminant plumes identified in the shallow soil or the uppermost shallow groundwater zones. The same conclusion applies for Partner Agency wells.

There is known contamination in the shallow groundwater zone at PCAs where shallow groundwater zone levels are within 56 feet of the surface or shallower. In addition, there is the potential for contamination in shallow soil or localized perched groundwater to migrate down to the Primary Production Aquifer with groundwater recharge. This potential exists under modeled existing conditions and under the Project. However, the presence of an aggregate thickness of fine-grained materials (which make up discontinuous low permeability zones underlying the shallow and perched groundwater zones with unsaturated zones that overlie the Primary Production Aquifer in most areas of the basin) reduces the possibility for vertical migration of contaminants from the perched or shallow groundwater zone to the underlying Primary Production Aquifer.

The existing and potential shallow groundwater zone contamination would need to migrate down to the Primary Production Aquifer to affect the ability of SFPUC and Partner Agency wells to meet drinking water standards. The shallow groundwater zone and Primary Production Aquifer are generally disconnected hydraulically in most areas; however, in those areas where there may be some level of connection, the Project would affect downward gradients and flow. The downward gradient with the Project would be smaller on average than predicted under modeled existing conditions, because the water levels in the Primary Production Aquifer would be higher (LSCE 2010). Consequently, the downward movement of contaminated groundwater from the shallow water-bearing zone would generally be less than under existing gradients in those areas where there may be some level of hydraulic connection. The vertical permeability of the sediments between the two zones is low, which means that downward movement of groundwater and contaminants is expected to be relatively slow. This low rate of movement would provide more time to detect and remediate contamination from surface sources before it reaches the Primary Production Aquifer.

Finally, each proposed well would be protected against contamination by the construction of an annular seal composed of sand/cement grout (see Chapter 3, Project Description, Section 3.5.1.1 [Construction

Methods for Production Wells]). For the above reasons, potential impacts on groundwater from PCAs would be *less than significant* for all proposed sites.

Elevated nitrate concentrations, especially in the Daly City and South San Francisco area where elevated levels occur in the Primary Production Aquifer, could be affected by Project pumping and in-lieu recharge. Nitrates in soils in the Project area are currently percolating towards the shallow groundwater. The Project would neither increase nor decrease the amount of nitrates that reach the shallow groundwater, because the Project would not change the amount of recharge from rainfall or the percolation rate of the soils. However, the Westside Basin Groundwater Model predicts that Project pumping and in-lieu recharge could result in changes in groundwater flow directions in areas where nitrate concentrations are currently elevated, which could transport nitrate in groundwater to production wells (Kennedy/Jenks May 2012e). If the location of nitrate concentrations changes such that nitrate concentrations in Project wells or Partner Agency wells increases above drinking water standards, this would be addressed through treatment, such as blending, to ensure that all drinking water standards for nitrate are met, as described in Chapter 3, Project Description, Section 3.4.2 (Production Wells and Associated Facilities).

Potential elevated VOC concentrations (i.e., PCE and TCE) in the Primary Production Aquifer and Deep Aquifer at monitoring wells located near Site 1[27] in Daly City and Site 11 in South San Francisco could be affected by Project pumping and in-lieu recharge. The Westside Basin Groundwater Model predicts that Project pumping and in-lieu recharge could result in changes in groundwater flow contours in areas and zones where VOC concentrations may currently be elevated (Kennedy/Jenks 2012e), which could transport VOCs in groundwater to Project or Partner Agency wells. Raw groundwater produced at Sites 1 and 11 would be the most likely to exceed drinking water standards due to the sites' co-location with detected contamination and the increase in groundwater flow to the Sites during Project Take Years. VOCs at these sites could also migrate towards other production wells such as Partner Agency wells in Daly City and South San Francisco as a result of changes in groundwater flow directions during Put and Hold Years. If the location of VOC concentrations were to change due to the Project such that VOC concentrations in Project wells or Partner Agency wells increase above target levels, this would be addressed through treatment, such as blending, to ensure that all drinking water standards for VOCs are met, as described in Chapter 3, Project Description, Section 3.4.2 (Production Wells and Associated Facilities).

Therefore, no violations of water quality standards would occur due to existing PCA contamination, nitrate concentrations, or elevated VOC concentrations, and the impact would be *less than significant*.

With respect to water quality concerns near the cemeteries, refer to Impact HY-14, relative to water quality degradation for constituents for which water quality standards do not exist.

[27] In October 2012, the monitoring well at Site 1 was resampled, and no VOCs were detected, indicating that the earlier detections may not be representative of the groundwater quality at Site 1 (SFPUC 2013c).

Project Operations May Mobilize or Spread Contamination in Groundwater or Cause Remediation Systems to Become Less Effective

This EIR evaluates the possibility of mobilizing or spreading existing areas of contamination due to increasing groundwater levels from in-lieu recharge of the Project. The in-lieu recharge that would occur during Put Years; i.e., reduced pumping on the part of the Partner Agencies in the Primary Production Aquifer at depths greater than 300 feet below ground surface is expected to indirectly lead to higher groundwater levels in the shallow, regionally continuous, groundwater zone (referred to as Model Layer 1 in the Westside Basin Groundwater Model). The Westside Basin Groundwater Model predicts that the maximum increase in groundwater levels is expected to occur at about Scenario Year 7 after several years of above-normal rainfall and at a time when the SFPUC Storage Account would be full. The Model identifies the Daly City and Colma areas as having shallow groundwater zone (Model Layer 1) levels well below 70 feet under modeled existing conditions. Although the Westside Basin Groundwater Model predicts that Primary Production Aquifer groundwater levels will rise up to 40 to 80 feet in the Daly City area and 5 to 40 feet in the Colma area due to the Project in Scenario Year 7, Primary Production Aquifer groundwater levels are predicted to remain below 70 feet, below where existing PCA contamination is located. Therefore, shallow PCA contamination in this area would not be mobilized or spread by the Project. (Kennedy/Jenks 2012e)

Table 5.16-16 (Predicted Groundwater Levels relative to Depth of Known Contamination) below lists existing municipal and proposed Project wells, together with the Primary Production Aquifer groundwater zone levels under modeled existing conditions (i.e., without operation of the Project) and with the Project, and the depth to water at PCAs within 2,000 feet of the wells. The depth-to-water values listed in the table have been rounded to the nearest 5 feet, to reflect accuracy of the topographic data on which they are based. The existing municipal and proposed Project wells in the Daly City and Colma areas have depths to water of at least 150 feet. The maximum increase in groundwater levels in the Primary Production Aquifer at the wells and PCAs in this area is estimated to be 70 feet or less. The deepest depth to waters at PCAs within 2,000 feet of these wells range from 21-56 feet indicating the presence of localized perched groundwater at these PCAs. The depth to water at the PCAs defines the maximum extent of soil contamination at the PCAs and the depth of any perched groundwater contamination at the sites. However, higher groundwater levels predicted to occur in the Primary Production Aquifer due to the Project would not rise to encountered depth to water at the PCAs and would not mobilize contamination at the PCAs.

This EIR also evaluates the possibility of the Project mobilizing or spreading existing areas of contamination by adversely affecting remediation systems due to changes in shallow groundwater zone levels. This could occur where shallow groundwater zone levels are shallower than 70 feet where remediation systems are assumed to operate. The Model identifies the South San Francisco, San Bruno, and Burlingame areas where this occurs. The Model predicts that shallow groundwater level zones would rise up to 10 feet in these areas with the Project (Kennedy/Jenks 2012e). These groundwater level increases would not substantially change the environment under which remediation is being undertaken and therefore would not be expected to affect the success of the remediation processes. Also, remediation systems typically are designed with some flexibility to accommodate natural fluctuations in groundwater levels. These areas also show no appreciable changes in shallow groundwater zone flow directions caused by the Project at either Scenario Year 7 when groundwater levels are predicted to be most shallow or at the end of the design drought when groundwater levels are predicted to be most deep

(Kennedy/Jenks May 2012e). Therefore, changing groundwater flow directions caused by the Project would not affect remediation processes.

Table 5.16-16 (Predicted Groundwater Levels relative to Depth of Known Contamination) below lists existing municipal and proposed Project wells and information about PCAs within 2,000 feet of the wells in the South San Francisco and San Bruno areas. Table 5.16-16 shows that modeled shallow groundwater zone levels have depths to water of less than 70 feet at a number of wells. The increases in shallow groundwater zone levels at these wells are approximately 5 feet in the South San Francisco area, and approximately 1 to 4 feet in the San Bruno area. Groundwater at PCAs within 2,000 feet of the wells is encountered at depths of 10 to 47 feet. These levels are close enough to modeled levels that groundwater encountered below the PCAs is considered part of the shallow groundwater zone. Therefore, contaminants in the shallow groundwater PCAs are already mobilized in the shallow groundwater zone. The concern is whether changing groundwater levels caused by the Project would adversely affect remediation systems in these areas, such as Chevron 9-8854 near the existing San Bruno well #17. Groundwater levels at this well are predicted to only increase 1 foot due to Project operations, which would not adversely affect remediation at this site.

Based on the above analyses, the potential impact from mobilization or spreading of contaminants in groundwater as a result of increased pumping would be *less than significant*.

Source: Kennedy/Jenks 2012e

Note:

(a) Depth to water for both modeled existing conditions and the Project is rounded to the nearest five feet because the Westside Basin Groundwater Model is not as accurate for specific groundwater levels at specific sites as when it is used to calculate Project effects (see further explanation in Section 5.1, Overview, Section 5.1.6 [Groundwater Modeling Overview]). Therefore, the values in the columns, "Modeled Existing Conditions Depth to Water" and "Maximum Increase in Groundwater Level due to the Project" may not add up exactly to the "Depth to Water with Project."

Impact Conclusion: Less than Significant

Impact HY-13: Project operation would not result in degradation of drinking water quality or groundwater quality relative to constituents for which standards do not exist. (Less than Significant)

Description of Water Quality Degradation

Operation of the Project could substantially degrade water quality if the groundwater pumped by the Project, Partner Agencies, and irrigation pumpers, after proposed treatment and/or blending as described in Chapter 3, Project Description, were degraded by constituents for which water quality standards do not exist.

Approach to Analysis

To determine whether groundwater pumped by the Project, Partner Agencies, and irrigation pumpers would be affected by non-regulated constituents, existing groundwater quality data were reviewed and detected non-regulated constituents were evaluated based on known health effects.

Groundwater quality in the Westside Groundwater Basin is monitored by the SFPUC and Partner Agencies through a network of production and monitoring wells as part of the semi-annual monitoring program that was initiated throughout the Basin in 2000. This network of wells includes existing water quality monitoring wells that have been installed at Sites 1, 2, 5, 7, 8, 9, 10, 11, 12, 13, 15, and 16 (see Chapter 3, Project Description, Section 3.4.3 [Facility Sites]), which were installed and sampled in 2008 and 2009.

The first series of monitoring wells were installed and sampled at Sites 2, 5, 7, 8, 10, 12, and 13 between December 2008 and January 2009. During the initial sampling of these wells, the volatile organic compound (VOC) acetone was detected in the groundwater sampled from each monitoring well at concentrations ranging from 6.5 to 34 micrograms per liter (μg/L). No Primary or Secondary MCL has been established for acetone and it is not included in the CDPH list of contaminants found in Title 22 of the California Code of Regulations. To assess the validity of acetone presence in the native groundwater, the monitoring well at Site 7 was re-sampled in October 2009 at two separate aquifer depths. In addition, groundwater from the monitoring wells at Sites 7, 8, and 10 were analyzed for acetone as part of SFPUC's 2010 Annual Groundwater Monitoring Program for the Westside Groundwater Basin (SFPUC 2011b). Acetone was not detected in any of the subsequent groundwater samples. The second series of monitoring wells were installed and sampled at Sites 9, 15, and 16 between June and September of 2009, and acetone was not detected in any of the wells. To further assess the validity of acetone presence in the native groundwater, the monitoring wells at Sites 2, 5, 7, 8, 10, and 12 were re-sampled in November 2012 at multiple aquifer depths. Acetone was not detected in any of the groundwater samples (SFPUC 2013c).

One other non-regulated VOC detected in groundwater monitoring wells is chloromethane. It is estimated that up to 99 percent of chloromethane that is released to the environment comes from natural sources, including chemical reactions that occur in the oceans or from chemical reactions that occur when materials like grass, wood, charcoal, and coal are burned (Kennedy/Jenks May 2012b, ATSDR 1998). In the past, chloromethane was widely used as a refrigerant, and also as a foam-blowing agent and as a pesticide or fumigant (ATSDR 1998). Chloromethane was detected in one groundwater sample collected from the monitoring well at Site 2 in January 2009. The sample was collected at a depth of 620 feet below ground surface and had a concentration of 0.77 μg/L, which is slightly above the laboratory detection limit of 0.5 μg/L. Chloromethane was not detected in other monitoring wells sampled. To assess the validity of chloromethane presence in the native groundwater, the monitoring well at Site 2 was re-sampled at a depth of 620 feet below ground surface in November 2012. Chloromethane was not detected in the groundwater sample (SFPUC 2013c).

Groundwater monitoring has also been performed to evaluate groundwater quality conditions in the vicinity of cemeteries. The initial samples were taken in September, October, and November 2009 at three different monitoring locations near cemeteries. Locations sampled included a multi-level monitoring well at Site 15 (screened at five depths from 190 to 580 feet below ground surface and each screen depth was sampled) located in the Golden Gate National Cemetery, a multi-level monitoring well at Site 7 (two depths sampled at 230 and 490 feet below ground surface) located near Cypress Lawn Cemetery, and the Site 13 multi-level monitoring wells (screened at four depths from 120 to 530 feet below ground surface and each screen depth was sampled). Samples were analyzed for aldehydes, including acetaldehyde. Acetaldehyde occurs naturally in certain foods, such as ripe fruits and coffee, and green plants produce acetaldehyde as they break down food (U.S. EPA 1994b). Acetaldehyde is also produced industrially for companies that make acetic acid and related chemicals, and is released into air or wastewater from facilities producing or using the chemical, as well as from the combustion and photo-oxidation of hydrocarbons (U.S. EPA 1994b).

Acetaldehyde was detected in two of the groundwater samples at concentrations of 1.0 and 2.0 μg/L, which were slightly above the laboratory detection limit of 1.0 μg/L. There is no established drinking water standard or health advisory for acetaldehyde. The Clean Air Act Amendments of 1990 list acetaldehyde as a hazardous air pollutant. The U.S. EPA has enacted restrictions for certain waste streams containing the chemical, and occupational exposure to acetaldehyde is regulated by the Occupational Safety and Health Administration, with a permissible exposure limit of 200 parts per million of air (U.S. EPA 1994a).

Specific groundwater sampling was undertaken in 2010 by the SFPUC to determine existing formaldehyde concentrations near cemeteries. No MCL has been established for formaldehyde, but a Notification Level of 100 μg/L has been set by the CDPH. Refer to Section 5.16.2.1 (Federal and State Regulations) for an explanation of Notification Levels. Formaldehyde was not detected in samples taken from monitoring wells located at Sites 7, 8, 10, 13, and 15 (all samples were non-detect for formaldehyde, i.e., less than 5 μg/L). The monitoring wells at Sites 7 and 15 are located at or adjacent to cemeteries; the monitoring wells at Sites 8 and 10 are located near cemeteries; and the monitoring well at Site 13 is located about 2,000 feet from the closest cemetery. The results indicate that there is no apparent existing groundwater contamination from cemeteries in the South Westside Groundwater Basin (Kennedy/Jenks 2012e). To assess the validity of acetaldehyde presence in the native groundwater, the monitoring wells at Sites 7 and 15 were re-sampled in November 2012. Acetaldehyde was not detected in either of the groundwater samples (SFPUC 2013c).

Impact Discussion and Significance Determination

As described in the Approach to Analysis above, several non-regulated constituents were initially detected in groundwater samples from monitoring wells at the proposed well sites, including acetone, acetaldehyde, and chloromethane. However, based on subsequent resampling, these detections were not confirmed (SFPUC 2013c).

Research on the possible long-term health ingestion of acetone suggests that the reference dose (the amount at which a daily exposure would likely not have deleterious non-cancer effects over a lifetime) is 0.9 milligrams per kilogram (mg/kg) per day for humans (Kennedy/Jenks May 2012e). This reference dose corresponds to a concentration in water of 31.5 mg/L (or 31,500 μg/L), which is approximately 1,000 times higher than the highest detected acetone concentration (34 μg/L) (Kennedy/Jenks May 2012e). In addition, as described above, the previously detected acetone concentrations have not been repeatable in subsequent groundwater sampling, and they are not considered to be representative of water quality conditions in the Westside Groundwater Basin (Kennedy/Jenks May 2012e). As a result, the potential impact on drinking water quality degradation from acetone in groundwater would be *less than significant*.

For chloromethane, the U.S. EPA has established one-day and 10-day drinking water health advisories for children (U.S. EPA 2012a). Health advisories from the U.S. EPA's Office of Water serve as informal technical guidance to assist federal, State, and local officials responsible for protecting public health, as needed. A 10-day health advisory for children is the concentration of a chemical in drinking water that is not expected to cause any adverse non-carcinogenic effects for up to 10 days of exposure. The one-day health advisory of 9,000 μg/L is approximately 9,000 times higher than the detected concentration of chloromethane (0.77 μg/L), and the 10-day health advisory of 400 μg/L is approximately 400 times higher than the detected concentration of chloromethane. In addition, as described above, the previously detected chloromethane concentration has not been repeatable in subsequent groundwater sampling (SFPUC 2013c). As a result, the potential impact on drinking water quality degradation from chloromethane in groundwater would be *less than significant*.

For acetaldehyde, no established drinking water standards or health advisories have been established. Acetaldehyde was detected in two of the groundwater samples at concentrations of 1.0 and 2.0 μg/L, which are slightly above the reporting limit of 1.0 μg/L. These concentrations are low and at levels normally found in the environment (Kennedy/Jenks 2012e). According to the U.S. EPA, acetaldehyde by itself is not likely to cause environmental harm at levels normally found in the environment (U.S. EPA 1994b). In addition, as described above, the previously detected acetaldehyde concentrations have not been repeatable in subsequent groundwater sampling (SFPUC 2013c). As a result, the potential impact on drinking water quality degradation from acetaldehyde in groundwater would be *less than significant*.

Impact Conclusion: Less than Significant

Impact HY-14: Project operation may have a substantial adverse effect on groundwater depletion in the Westside Groundwater Basin over the very long term. (Less than Significant with Mitigation)

Description of Groundwater Depletion

Impacts related to groundwater depletion would be significant if Project operations were to reduce groundwater supplies or interfere with groundwater recharge in a manner that would result in a substantial regional deficit in aquifer storage, and that deficit in aquifer storage would lead to insufficient water supply to support existing or planned land uses.

Approach to Analysis

To assess potential changes in the volume of groundwater stored in the Westside Groundwater Basin, the existing storage volume was estimated and then compared to the storage volume predicted at the end of the 47-year simulation period with Project operations. This analytical approach provides a conservative estimate of the magnitude of impacts from Project operation on overall long-term groundwater storage using the modeled data for the 47-year simulation period. A volumetric calculation was made to estimate the total volume of groundwater in the Westside Groundwater Basin in 2009, based on the volume of the aquifer from the Westside Basin Groundwater Model and an estimate of the available pore space, or porosity, within the aquifer to store water. The volume of the aquifer in the Westside Basin Groundwater Model was based on measured groundwater levels throughout the Basin (Kennedy/Jenks 2012b). The total storage volume calculated by the Westside Groundwater Basin Model is not intended to be the groundwater volume available for recovery, the sustainable yield of the Basin, or other functional definition of storage. Instead, a volumetric estimate of this type is intended to provide context for evaluating the scale of aquifer storage changes that could be caused by the Project. This analysis compares the total groundwater storage changes from the Project to the total groundwater in the Basin. The purpose of this comparison is to provide a sense of the scale of the potential aquifer storage changes relative to the size of the groundwater basin. It should be noted that the Westside Basin Groundwater Model, from which the groundwater storage volumes are derived, has a root mean square error[28] of four percent with respect to basin-wide groundwater levels (Kennedy/Jenks 2012b). Assuming that this root mean square error value also applies directly to modeled groundwater storage then it is possible that any predicted changes in groundwater storage of less than four percent may be attributable to the accuracy of the Model and may not necessarily indicate a change attributable to the modeling scenario being analyzed.

Groundwater depletion may have negative effects on the specific uses of groundwater to support existing or planned land uses; therefore, this EIR evaluates impacts separately on groundwater resources relative to well interference, subsidence, seawater intrusion, groundwater-surface water interactions, and water quality. Refer to Impacts HY-7 through HY-14 for specific evaluations of these other potential impacts.

Previous Analysis

Daly City conducted a model simulation (Version 3.1) consisting of a 51-year continuation of existing or anticipated land and water use conditions and Partner Agency pumping rates consistent with those used in the GSR Project-specific and cumulative model scenarios. The Hydrofocus study concluded that planned groundwater pumping, including the GSR Project, would not result in substantial long-term storage decline in the basin. (HydroFocus 2011)

---

[28] Root mean square error is a statistical measure that evaluates the average difference (or residual) between modeled and observed parameters and provides a measure of the overall error in the model (Kennedy/Jenks 2012a).

Modeled Existing Conditions

Based on the Westside Basin Groundwater Model, the groundwater storage volume in the Westside Groundwater Basin was calculated based on June 2009 groundwater levels. To facilitate this calculation, the Westside Groundwater Basin was defined as three onshore subareas[29]. The volume of the offshore subareas of the Westside Groundwater Basin underlying the Pacific Ocean and San Francisco Bay were not included in the analysis conducted for this EIR. The results of the volumetric calculations for the three onshore subareas are summarized below (Kennedy/Jenks 2012b):

- The Serra Block subarea was defined as the portion of the Basin east of the Pacific coast and west of the Serra Fault (where it is located onshore). The total estimated groundwater volume in this subarea is 340,000 af.

- The North Westside Basin subarea was defined as the portion of the Basin north of the San Mateo-San Francisco County line and east of either Ocean Beach or the Serra Fault (where it is located onshore). The total estimated groundwater volume in this subarea is 223,000 af.

The South Westside Basin subarea was defined as the portion of the Basin east of the Serra Fault, south of the San Mateo-San Francisco County line and west of SFO. The total estimated groundwater volume in this subarea is 513,000 af. The total estimated groundwater volume in 2009 in the onshore Westside Groundwater Basin using this method is 1,076,000 af (Kennedy/Jenks 2012b).

Over the 47 years of the hydrologic modeling sequence, the predicted 28,000 af decline (which includes the hypothetical design drought) under the modeled existing conditions is 2.6 percent of the estimated total groundwater storage of 1,076,000 af in 2009. It should be noted that the estimated total groundwater storage of 1,076,000 af is not equivalent to the sustainable yield of the basin. Some of the water in the basin has not proven to be a resource, and the accessibility to the total storage amount is not known at this time.

The Westside Basin Groundwater Model predicts that under the modeled existing conditions (i.e., without the Project), groundwater storage in the groundwater basin is declining by approximately 597 afy, or approximately 28,000 af over the 47 years of the hydrologic modeling sequence. The predicted 28,000-af decline in groundwater storage is primarily a result of the assumptions used in the modeling, which conservatively included a design drought consistent with the hydrologic modeling assumptions included in the WSIP PEIR. The design drought used in the Westside Basin Groundwater Model was created for planning purposes and represents drought conditions that are worse than anything indicated in recent historic records, as discussed in Section 5.1, Overview, section 5.1.6 (Groundwater Modeling Overview). Over the 47 years of historic hydrologic records used to develop the model, no drought occurred that was as severe as the design drought. Incorporation of a design drought into the Westside Basin Groundwater Model results in approximately 20 inches of rainfall less in the simulation than

[29] The analysis of groundwater depletion is not intended to address sub-basin or site-specific changes in groundwater storage. Impacts that may potentially result from sub-basin or site-specific changes in groundwater storage are addressed under the other groundwater impact categories, such as well interference and seawater intrusion.

otherwise indicated by historic records, which is nearly equivalent to losing a full year of precipitation and its associated recharge for the entire Basin. The projected 597 af of annual average decline (which would result in 28,000 af of decline in storage over the 47-year hydrologic modeling period) in groundwater storage can largely be attributed to the conservative inclusion of the design drought into the Westside Basin Groundwater Model (Kennedy/Jenks 2012b, HydroFocus 2011). Nonetheless, with the conservative use of a design drought, as included in the Westside Basin Groundwater Model, the Westside Groundwater Basin is predicted under the modeled existing conditions to lose a small amount of storage over the long-term, as further discussed below.

Impact Discussion and Significance Determination

The total decrease in groundwater storage volumes due to Project operation is predicted to result in a decline of approximately 416 afy more than under the modeled existing conditions (that is, without the Project). Over the 47-year simulation period, the total decline in groundwater storage is predicted to be approximately 20,000 af. This decline can be attributed to the fact that the storage efficiency of the Basin is less than 100 percent, that is, the stored groundwater naturally moves to other locations within the basin and/or out of the basin (e.g., water might move from an area of high groundwater levels to an area of low groundwater levels). Such movement of groundwater out of the Basin is known as "leakage." As described by Kennedy/Jenks (2012b), leakage would be highest when groundwater levels are highest (such as would be the case during prolonged Hold Periods) and lowest when groundwater levels are lowest (such as would be the case during the design drought). The effect of these losses would be that not all of the water added into the SFPUC Storage Account during normal and wet periods would be available for pumping during dry periods. As described in Chapter 3, Project Description, Section 3.8.1 (Operating Agreement), this possibility would be accounted for under the proposed Operating Agreement, whereby the Operating Committee would monitor and track the SFPUC Storage Account, including any leakage from the Basin attributable to the Project pumping.

The predicted 20,000 af decline in groundwater storage due to Project operations, as compared to modeled existing conditions over the 47-year simulation, represents about 1.8 percent of the estimated total groundwater volume in the onshore portion of the Westside Groundwater Basin. Even though this decline is small, the Project is predicted to cause an incremental depletion of groundwater storage over the long-term, which is conservatively deemed a *significant* impact because over the very long-term this could result in a substantial regional deficit in aquifer storage that may not fully support existing or planned land uses, given the heavy reliance of local jurisdictions, golf clubs, and cemeteries within the study area on groundwater for their water supply.

Mitigation Measure M-HY-14 (Prevent Groundwater Depletion) requires thorough accounting methods for Basin losses based on actual experience operating the Project, and allows the SFPUC to convert Hold Years to additional Put Years when surplus surface water is available. Such accounting methods would ensure that any Basin losses caused by the Project would be adequately reflected in the SFPUC Storage Account. The provision in the mitigation measure for additional Put Years would at least partially offset the estimated losses from the Basin as a result of the Project by reducing Partner Agency pumping from their existing wells during those years. If, however, the additional in-lieu recharge is not sufficient to offset basin storage losses identified by the Operating Committee, Mitigation Measure M-HY-14 requires that the Project pumping be restricted to extract only the volume of water in the SFPUC Storage Account, which would be adjusted to account for Basin storage losses. Therefore, Mitigation Measure M-HY-14 would reduce impacts of the Project on long-term depletion of groundwater storage to *less-than-significant* levels.

Mitigation Measure M-HY-14 (Prevent Groundwater Depletion) would not cause impacts to groundwater beyond those already identified in this EIR, because additional Put Years would only replace small volumes of overall basin groundwater storage which may be lost and would neither increase nor decrease groundwater levels more than would occur under the Project as defined in Chapter 3, Project Description (SFPUC 2013a).

Mitigation Measure M-HY-14: Prevent Groundwater Depletion

The SFPUC, working in conjunction with the GSR Operating Committee, shall develop and adopt an SFPUC Storage Account monitoring program that will determine the amount of water available for extraction from the SFPUC Storage Account and develop accounting rules that will account for losses from the Basin due to leakage, consistent with the terms of the Operating Agreement between the SFPUC and the Partner Agencies. The SFPUC shall develop the SFPUC Storage Account monitoring program to determine the balance in the SFPUC Storage Account based on actual experience operating in the Westside Groundwater Basin as proposed under the GSR Project. The SFPUC Storage Account monitoring program will use data from metered SFPUC in-lieu water deliveries to the Partner Agencies and regularly measured changes in groundwater elevations during a series of Put and Hold Years to determine the volume of stored water while developing rules to account for losses in groundwater storage, based on generally accepted principles of groundwater management.

To replace water losses in the SFPUC Storage Account due to Basin losses, the SFPUC may deliver additional surface water to the Partner Agencies when surplus surface water is available, creating additional in-lieu recharge to the Westside Basin. This conversion of wet Hold Years to additional Put Years would offset the estimated losses from the Basin as a result of the Project by reducing Partner Agency pumping from their existing wells during those years. Such additional surface water deliveries to the Partner Agencies shall not increase storage in the SFPUC Storage Account above 60,500 af.

The GSR wells shall only be pumped when there is a positive balance in the SFPUC Storage Account, which will be adjusted for losses from the Basin due to leakage caused as a result of the Project. If the additional in-lieu recharge is not sufficient to offset losses identified by the Operating Committee as caused by storage losses from the basin, the GSR wells will only be operated to extract the volume of water in the SFPUC Storage Account.

Impact Conclusion: Less than Significant with Mitigation

5.16.3.8 Cumulative Impacts and Mitigation Measures

Impact C-HY-1: Project construction could result in a cumulatively considerable contribution to cumulative impacts on surface water hydrology and water quality. (Less than Significant with Mitigation)

The geographic scope for the analysis of potential cumulative surface water hydrology and water quality impacts in the study area, due to construction activities, consists of individual facility sites and the surrounding watershed lands. The analysis of potential cumulative impacts on surface water hydrology and water quality considers those cumulative projects listed in Table 5.1-3 (Projects Considered for Cumulative Impacts) and shown on Figure 5.1-3 (Location of Projects Considered in the Cumulative Analysis). This analysis focuses on the other past, present, and reasonably foreseeable future projects that could adversely affect water quality during construction of the Project, but especially on activities that involve ground disturbing activities, the placement of fill or structures within the 100-year flood hazard zone, and an increase in impervious surfaces that could be occurring concurrently with construction of the Project.

Degradation of Water Quality

Construction activities associated with the GSR Project could result in the degradation of water quality from increased soil erosion and associated sedimentation of water bodies, as well as an accidental release of hazardous materials, as analyzed above in Impact HY-1. The discharged groundwater from GSR well development, well pumping tests, initial disinfection, and excavation dewatering could also result in increased sources of silt-laden runoff resulting in on- or off site erosion or siltation and/or the violation of water quality standards and degradation of water quality (Impact HY-2). It is assumed that several of the cumulative projects listed in Table 5.1-3 (Projects Considered for Cumulative Impacts), particularly those projects located in close proximity to the proposed well sites, could adversely affect some of the same water bodies during construction. In particular, the proposed SFPUC Peninsula Pipelines Seismic Upgrade (PPSU) Project (cumulative project D-1 through D-3) includes seismic upgrades to SFPUC existing pipelines that deliver water from the Harry Tracy Water Treatment Plant to the regional water system. Pipeline work for the PPSU Project would occur within the construction boundaries of GSR Sites 8 and 17 (Alternate). Construction of the PPSU Project and the GSR Project would overlap geographically and may use some of the same staging areas during construction. Therefore, cumulative impacts from the proposed SFPUC PPSU Project related to surface water quality and sedimentation, such as potential erosion from vegetation removal, grading, and excavation, could be significant, and the GSR Project's contribution to this cumulative impact could be cumulatively considerable given that its construction has the potential to result in *significant* construction-related water quality impacts.

However, as discussed in Impact HY-1, the GSR Project's potential construction-related water quality impacts related to soil erosion and sedimentation and accidental releases of hazardous materials would be reduced to *less-than-significant* levels with implementation of Mitigation Measure M-HY-1 (Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan); this measure requires the preparation and implementation of a SWPPP for sites that would exceed one acre of land disturbance (i.e., Sites 3, 4, 5, 6, 7, 12, 13, and 14) and an erosion and sedimentation control plan for all other sites to protect water quality during construction. The plans would address erosion and sedimentation control measures, waste management, and hazardous materials pollution control, and the necessary inspection and reporting requirements to document compliance. In addition, Project-related water quality impacts related to discharges of dewatering effluent from well development and testing would be *less than significant* with implementation Mitigation Measure M-HY-2 (Management of Well Development and Pump Testing Discharges). This measure requires the preparation of a Project-specific dewatering plan specifying how the water would be collected, contained, treated, monitored, and discharged to the local storm drainage system or sanitary sewer system. Therefore, potential impacts related to discharges of treated water from newly installed wells and pipelines during construction into the storm drain or sanitary sewer system would also be *less than significant as mitigated*.

This analysis assumes that most of the cumulative projects in Table 5.1-3 (Projects Considered for Cumulative Impacts) would be subject to the NPDES construction general construction permit and would be required to implement BMPs to protect water quality during construction, including measures to avoid water quality impacts from dewatering discharges from excavation and from well testing discharges, such as the Daly City "A" Street Well Replacement Project (cumulative project C). Other SFPUC projects that would involve discharges of treated water from the regional water system, such as the San Francisco Groundwater Supply (SFGW) Project (cumulative project A-1 through A-6) and the PPSU Project (cumulative project D-1 through D-3), would be subject to the Waste Discharge Requirements for the SFPUC Drinking Water Transmission System. Because the NPDES construction general permit and the Waste Discharge Requirements for the SFPUC Drinking Water Transmission System were developed in consideration of regional water quality issues, compliance with regulatory requirements would serve to limit the potential for significant cumulative water impacts to result from the construction of these projects. With implementation of Mitigation Measure M-HY-1 (Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan) and Mitigation Measure M-HY-2 (Management of Well Development and Pump Testing Discharges) and compliance with the Waste Discharge Requirements for the SFPUC Drinking Water Transmission System, the GSR Project's potential contribution to any such cumulative water quality impacts would therefore not be cumulatively considerable (*less than significant with mitigation*).

Increased Flood Hazard

None of the present or probable future projects considered in the cumulative impact analysis and listed in Table 5.1-3 (Projects Considered for Cumulative Impacts) would be located in a mapped flood hazard zone according to the FEMA Flood Insurance Rate Mapping (San Francisco 2008; San Mateo County 2012). As such, there would be no cumulative impacts from increased flood hazard. Although a portion of Site 9 would be located in the FEMA mapped 100-year flood hazard zone, the only impacts would be Project specific and would not combine with any potential impacts from the cumulative projects. As discussed in Impact HY-4, Site 9 would not exacerbate flooding as the building would be elevated above the 100-year flood zone and the at-grade parking area would have a negligible effect on impeding or redirecting flood flows (*no impact*).

New Impervious Surfaces

As discussed under Impact HY-4, the GSR Project would result in the creation of new impervious surfaces, which could increase erosion and siltation, or increase the rate or amount of stormwater runoff, or cause flooding on- or off-site. Other cumulative projects listed in Table 5.1-3 (Projects Considered for Cumulative Impacts), including well facilities associated with the SFGW Project (cumulative project A-1 through A-6), residential and commercial facilities associated with the Mission & McLellan Project (cumulative project F) and the Centennial Village Project (cumulative project I), would also create new impervious surfaces and could result in the similar localized effects, resulting in a potentially *significant* cumulative impact on hydrology. However, due to the relatively minor increase in impervious surface areas (e.g., 205 feet to 3,675 square feet) associated with construction of individual GSR facilities, the GSR Project's contribution to this potential impact on hydrology would not be cumulatively considerable (*less than significant*).

Impact C-HY-2: Operation of the proposed Project would result in a cumulatively considerable contribution to cumulative impacts related to well interference. (Significant and Unavoidable with Mitigation)

The geographic scope for the analysis of potential cumulative impacts on well interference in the study area is the area within three miles of each of the GSR wells, because if an existing irrigation well were located within 1.5 miles of a GSR Project well on one side, and a cumulative project well within 1.5 miles on the other side of it, hypothetically, it could be affected by both. Table 5.1-3 (Projects Considered for Cumulative Impacts) and their locations are shown on Figure 5.1-3 (Location of Projects Considered in the Cumulative Analysis).

Two cumulative projects, the SFGW Project (cumulative project A1 to A6) and the Holy Cross Cemetery Expansion Project (cumulative project E) would increase pumping in the Westside Groundwater Basin, potentially leading to lower groundwater levels. One cumulative project, the Vista Grande Drainage Basin Improvement Project (cumulative Project B) would discharge treated stormwater to Lake Merced, which could – in turn – potentially increase groundwater levels near Lake Merced.

Additional drawdowns due to the proposed SFGW Project are estimated using the Westside Basin Groundwater Model. These potential drawdowns are combined with estimated groundwater levels for the GSR Project to estimate the combined effects of both projects (Fugro 2012a). Additional drawdowns due to the Holy Cross Cemetery Expansion Project are estimated to be negligible relative to well interference impacts (Fugro 2012c). The Vista Grande Drainage Improvements Project would not increase well interference, because it would not decrease groundwater levels. Because pumping under cumulative conditions would be at maximum levels during a drought, this analysis focuses on the well interference that could occur at the end of the design drought.

The San Francisco Golf Club, Olympic Club, and Lake Merced Golf Club wells are the only existing irrigation wells where both the SFGW Project wells and the GSR Project wells would result in combined groundwater level effects (Fugro 2012a). Table 5.16-17 (Estimated Static and Pumping Depth to Water at the End of the Design Drought with Cumulative Projects) shows the projected static and pumping depth to water at wells at these three golf clubs at the end of the design drought during pumping by the cumulative projects. When the wells at the three golf clubs are not being pumped (i.e., static condition), groundwater levels are projected to decrease about 4 to 6 feet more from the cumulative pumping than with the GSR Project pumping alone. When the wells are active (i.e., pumping condition), groundwater levels are projected to decrease about 6 feet more from the cumulative pumping than from the GSR Project pumping alone.

TABLE 5.16-17
Estimated Static and Pumping Depth to Water at the End of the Design Drought with Cumulative Projects

Existing Irrigation Well	Estimated Static Depth to Water (feet below ground surface)			Estimated Pumping Depth to Water (feet below ground surface)		
	With GSR Project	With Cumulative Projects	Difference	With GSR Project	With Cumulative Projects	Difference
SF Golf Club #2	196	202	6	228	234	6
Olympic Club #8	136	142	6	195	201	6
Olympic Club #9	136	142	6	164	170	6
Lake Merced Golf Club #3	358	362	4	INA	INA	INA

Note:

INA: Information on this existing irrigation well that would allow calculation of impacts of the Project on production capacity is not available.

Cumulative pumping and the resulting groundwater level decreases identified above in Table 5.16-17 are projected to affect the pump discharge rates of existing irrigation wells, as shown in Table 5.16-18 (Estimated Pump Discharge Rate at the End of the Design Drought with Cumulative Projects). Pump discharge rates at the three golf clubs are projected to decrease due to cumulative pumping approximately one to three percent more than from the GSR Project pumping alone.

TABLE 5.16-18
Estimated Pump Discharge Rate at the End of the Design Drought with Cumulative Projects

Existing Irrigation Well	With GSR Project (gpm)	With Cumulative Projects (gpm)	Percent Reduction Compared to GSR Project
San Francisco Golf Club #2	660	655	1
Olympic Club #8	935	910	3
Olympic Club #9	660	640	3
Lake Merced Golf Club #3	INA	INA	INA

Source: Fugro 2012a

Note:

INA: Information on this existing irrigation well that would allow calculation of impacts of the Project on pump discharge rate is not available.

Table 5.16-19 (Estimated Peak Demands and 12-Hour Production Capacities) compares 12-hour production capacities for each well potentially affected by the cumulative projects. Also included in calculations in Table 5.16-19 is the increased demand resulting from the reasonably foreseeable 30-acre expansion of Holy Cross Cemetery to a future total area of 180 acres. Production capacities of the existing wells at Holy Cross Cemetery are assumed to be the same in the future as they are now. As stated above, this increased demand at Holy Cross Cemetery does not result in additional drawdowns that cause well interference impacts, but the analysis evaluates whether well interference from the Project affects the ability of Holy Cross Cemetery to meet its expansion demand.

TABLE 5.16-19
Estimated Peak Demands and 12-Hour Production Capacities

Land Use	Estimated Peak Demand (af per 12-hour period)	Estimated 12-Hour Production Capacity for Primary, Active, and Secondary Wells (af)		
		Existing Conditions	With GSR Project	With Cumulative Projects
San Francisco Golf Club	0.3	1.5	1.5	1.4
Olympic Club	0.1	3.7	3.5	3.4
Lake Merced Golf Club	0.2	INA	INA	INA
Holy Cross Cemetery	2.6	3.5	2.9	2.9

Note:

INA: Information on the existing irrigation well that would allow calculation of impacts of the Project on production capacity is not available.

The wells at the Olympic Club and San Francisco Golf Club would likely meet their estimated peak demands even with maximum cumulative pumping at the end of the design drought. The pumping groundwater level under the cumulative effects of the projects is estimated to decrease below the top of the screen at Olympic Club Well #8, and dewatering the 400 feet of screen by 1 foot would have a negligible impact on well capacity, because the 1-foot drawdown below the top of well screen would be a small percentage of the screen interval. Nevertheless, there is a risk of well or pump damage from lowering groundwater levels below the top of the screen. However, this risk could be avoided by pumping only from Olympic Club Well #9 when groundwater levels are low during drought conditions. Well #9 has a 12-hour discharge capacity of 1.4 af that can meet peak groundwater demand of the Olympic Club. It is assumed that the entire Olympic Club irrigation system can be supplied by Well #9 alone because Well #8 and #9 are located near each other. Therefore, the cumulative projects would have *less-than-significant* cumulative impacts relative to well interference at the Olympic Club and San Francisco Golf Club.

The impacts of the cumulative projects on the Lake Merced Golf Club wells would be slightly greater than under the proposed Project. The cumulative impact of these projects together would be *significant* at the Lake Merced Golf Club, given that the GSR Project by itself would have *significant* impacts. The contribution of the GSR Project to this significant cumulative impact would, therefore, be considerable (*significant*).

The well interference water level and pump capacity impacts at Holy Cross Cemetery are the same with the GSR project and the cumulative projects. The well at Holy Cross Cemetery would meet peak demand even with its expansion. Therefore, there would be *less-than-significant* cumulative impacts relative to well interference at Holy Cross Cemetery.

With implementation of Mitigation Measure M-HY-6 (Ensure Existing Irrigators' Wells Are Not Prevented from Supporting Existing or Planned Land Use Due to Project Operation), the potentially *significant* cumulative impact on well interference would be reduced in a similar manner as described above for the Project-specific impacts. Mitigation Action #6, Replace Irrigation Well, would be effective at reducing the Project's contribution to cumulative impacts to less-than-considerable levels, because the replacement well could be constructed deep enough to access an aquifer with sufficient water to meet peak irrigation demand while simultaneously avoiding any cumulative effects related to well interference (SFPUC 2012c). Therefore, Mitigation Measure M-HY-6 would reduce the impacts of well interference to a level where existing and planned land uses would be supported, except that the feasibility of the mitigation measure cannot be assured until the existing irrigation well owners have agreed to allow the mitigation to take place on their property. Because such assurance has not yet been provided, Impact C-HY-2, with implementation of Mitigation Measure H-HY-6, is conservatively deemed to be cumulatively considerable (*significant and potentially unavoidable with mitigation)*.

Impact C-HY-3: Operation of the proposed Project would not result in a cumulatively considerable contribution to cumulative impacts related to subsidence. (Less than Significant)

The geographic scope for the analysis of potential cumulative impacts on subsidence in the study area is the entire Westside Groundwater Basin as shown on Figure 2-1 (Project Vicinity Map). Table 5.1-3 (Projects Considered for Cumulative Impacts) and their locations are shown on Figure 5.1-3 (Location of Projects Considered in the Cumulative Analysis).

Two cumulative projects, the SFGW Project (cumulative project A-1 to A-6) and the Holy Cross Cemetery Expansion Project (cumulative project E) would increase pumping in the Westside Groundwater Basin, potentially leading to lower groundwater levels. One cumulative project (the Vista Grande Drainage Basin Improvement Project [cumulative project B]) would discharge treated stormwater to Lake Merced, which could – in turn – potentially increase groundwater levels near Lake Merced. Each of these cumulative projects, together with the continuation of existing pumping in the Westside Groundwater Basin, have been included in the Westside Basin Groundwater Model (described in Section 5.1, Overview, Section 5.1.6 [Groundwater Modeling Overview]), so predicted groundwater levels for the cumulative conditions scenario include the effects from operation of the cumulative projects.

The difference in predicted groundwater levels between the modeled existing conditions and the cumulative conditions scenario would be up to 61 feet lower at Lake Merced[30], up to 25 feet lower at the Sunset area of San Francisco, up to 146 feet lower at GSR Site 8, and up to 151 feet lower at GSR Site 13.

Table 5.16-20 (Estimated Subsidence Due to Cumulative Projects and the GSR Project) lists estimates of land subsidence due to the cumulative conditions scenario, as well as the portion of the subsidence due to the GSR Project, at the four selected locations. The subsidence estimates are taken from the Westside Basin Groundwater Model results relative to the difference in groundwater levels between the modeled existing conditions scenario and the cumulative conditions scenario.

[30] The lower groundwater levels at Lake Merced are reported from the Primary Production Aquifer, not the Shallow Aquifer. The Primary Production Aquifer at Lake Merced is not in direct hydrologic connection with the lake.

TABLE 5.16-20
Estimated Subsidence Due to Cumulative Projects and the GSR Project (in inches)

Site ID	Estimated Subsidence from Cumulative Projects	Estimated Subsidence from GSR Project
San Francisco, eastern Lake Merced	2.8	1.0
San Francisco, Sunset area	1.6	— (a)
Colma, GSR Site 8	2.7	2.7
South San Francisco, GSR Site 13	3.5	3.4

Source: Fugro 2012b

Note:

(a) The contribution of the GSR Project to subsidence in the Sunset area of San Francisco would be so small that it cannot be reliably estimated.

The estimated subsidence due to the cumulative projects ranges between 1.6 and 3.5 inches. Estimated subsidence due to the cumulative projects at each of the locations is less than the significance threshold of six inches for structures, pipelines, and drainage patterns. Estimated subsidence due to operation of the cumulative conditions scenario (i.e., the cumulative projects plus the GSR Project) at each of the four locations is also less than the significance threshold of 1 foot set for flooding impacts on land within a 100-year flood zone. For these reasons, the potential cumulative impact on subsidence from operation of the cumulative projects would be *less than significant* for structures, changes to drainage patterns, and flooding *(less than significant)*.

Impact C-HY-4: Operation of the proposed Project would not have a cumulatively considerable contribution to seawater intrusion. (Less than Significant)

The geographic scope for the analysis of potential cumulative impacts relative to seawater intrusion in the study area is the entire Westside Groundwater Basin as shown in Figure 2-1 (Project Vicinity Map). Table 5.1-3 (Projects Considered for Cumulative Impacts) and their locations are shown on Figure 5.1-3 (Location of Projects Considered in the Cumulative Analysis).

Two cumulative projects, the SFGW Project and the Holy Cross Cemetery Expansion Project (cumulative project A-1 to A-6 and E, respectively) would increase pumping in the Westside Groundwater Basin, potentially leading to lower groundwater levels. One cumulative project, the Vista Grande Drainage Improvements Project (cumulative project B) would discharge treated stormwater to Lake Merced, which could – in turn – potentially increase groundwater levels near Lake Merced. Each of these cumulative projects, together with the continuation of existing pumping in the Westside Groundwater Basin, have been included in the Westside Basin Groundwater Model, so that groundwater levels are also predicted for the effects from operation of the cumulative projects.

The Westside Basin Groundwater Model cumulative simulation shows that groundwater levels in the South Westside Groundwater Basin are predicted to be similar to those of the GSR Project scenario. Because the SFGW Project would be located in the North Westside Groundwater Basin, the overall effect of the SFGW Project on the South Westside Groundwater Basin is expected to be minimal. However, the SFGW Project includes substantial pumping that would lower groundwater levels in the North Westside Groundwater Basin.

Potential for Cumulative Seawater Intrusion in the North Westside Groundwater Basin

Shallow Aquifer

The Westside Basin Groundwater Model predicts that the cumulative projects would result in average groundwater levels in the Shallow Aquifer that would be generally lower than the average groundwater levels under modeled existing conditions (Kennedy/Jenks 2012c). These lower groundwater levels would tend to promote seawater intrusion. The estimated change in groundwater levels, measured at monitoring well clusters in the North Westside Groundwater Basin, ranges between a rise of 0.3 feet and a drop of 20.3 feet. The average predicted drop in groundwater levels, estimated at monitoring well clusters in the North Westside Groundwater Basin, are groundwater drops of between 1.4 and 10.4 feet.

The Westside Basin Groundwater Model results also show that groundwater levels in the Shallow Aquifer are predicted to be below the exclusion head between 0 and 86 percent of the time for different locations during the hydrologic sequence under the cumulative scenario. Estimated groundwater levels in the Shallow Aquifer would never be below the exclusion head under modeled existing conditions (i.e., without the cumulative projects). Therefore, the cumulative scenario is expected to result in substantially more time when groundwater levels would be below the exclusion head.

Under the cumulative conditions scenario, the average groundwater flux from the Westside Groundwater Basin to the Pacific Ocean is predicted to be 103 afy, which is 153 afm lower than predicted under modeled existing conditions (Kennedy/Jenks 2012c). This decreased flux would tend to reduce the amount of groundwater outflow to the Pacific Ocean or allow incipient or additional seawater intrusion into the Westside Groundwater Basin. Although these decreased flux estimates are not specific to the Shallow Aquifer, they suggest that, generally, less groundwater would flow out to the ocean under the cumulative scenario than under modeled existing conditions.

The Westside Basin Groundwater Model predicts that groundwater level contours for the Shallow Aquifer under the cumulative scenario in western San Francisco (around the SFGW Project's West Sunset Playground well) would likely have an increased potential for seawater intrusion (Kennedy/Jenks 2012c). South of the West Sunset Playground well, the groundwater level contours suggest a smaller, although still measurable, potential for increased seawater intrusion compared to modeled existing conditions.

Primary Production and Deep Aquifers

The Westside Basin Groundwater Model predicts that the cumulative conditions scenario would result in average groundwater levels in the Primary Production and Deep Aquifers lower than the average groundwater levels under modeled existing conditions (Kennedy/Jenks 2012c). These lower groundwater levels could lead to seawater intrusion. The range of groundwater elevation changes in the Primary Production Aquifer, estimated at monitoring wells in the North Westside Groundwater Basin, is between a rise of 2.3 feet and a drop of 16 feet. The average drop in Primary Production Aquifer groundwater levels, estimated at monitoring well clusters in the North Westside Groundwater Basin, would be between 4.0 and 8.5 feet at various locations. The range of groundwater elevation changes in the Deep Aquifer, estimated at monitoring wells in the North Westside Groundwater Basin, is between a rise of 1.1 feet and a drop of 16.9 feet. The average drop in Deep Aquifer groundwater levels is predicted to be between 1.3 and 3.9 feet at the various locations.

The Westside Basin Groundwater Model results predict that the cumulative conditions scenario would cause groundwater levels in the Primary Production Aquifer to be below the exclusion head 100 percent of the hydrologic sequence. This is slightly greater than the 99 to 100 percent of time that groundwater levels in the Primary Production Aquifer are predicted to be below the exclusion head under modeled existing conditions. As a result, the cumulative scenario is expected to cause a small increase in time when groundwater levels would be below the exclusion head.

Groundwater levels in the Deep Aquifer are also predicted to be below the Deep Aquifer exclusion head 100 percent of the hydrologic sequence under cumulative conditions, which would be the same as predicted under modeled existing conditions.

Therefore, in the North Westside Groundwater Basin, the cumulative scenario is predicted to decrease groundwater levels on average, creating an increased risk of seawater intrusion, which would be a *significant* cumulative impact on groundwater quality. However, the GSR Project is not predicted to cause decreased average groundwater levels in the North Westside Groundwater Basin in excess of those predicted under modeled existing conditions. Therefore, the GSR Project would not have a considerable contribution to the cumulative impact relative to seawater intrusion in the North Westside Groundwater Basin (*less than significant*).

Potential for Cumulative Seawater Intrusion in the South Westside Groundwater Basin

Shallow groundwater zone

The Westside Basin Groundwater Model results predict that average groundwater levels in the shallow groundwater zone under the cumulative conditions scenario would be equal to or higher than the average groundwater levels predicted under modeled existing conditions (Kennedy/Jenks 2012c). These higher groundwater levels under the cumulative scenario would better impede seawater intrusion as compared to modeled existing conditions. The change in groundwater levels, estimated at monitoring well clusters in the South Westside Groundwater Basin range between a rise of 3.0 feet and a drop of 0.2 feet. The average rise in groundwater levels is predicted to be between 0.7 and 2.0 feet at various locations.

Groundwater levels in the shallow groundwater zone under the cumulative conditions scenario are predicted to be below the exclusion head seven to 100 percent of the time during the 47-year hydrologic sequence. Simulated groundwater levels in the shallow groundwater zone are predicted to be below the single aquifer exclusion head 10 to 100 percent of the hydrologic sequence under modeled existing conditions. Therefore, the cumulative scenario is not predicted to result in additional time when groundwater levels would be below the exclusion head.

The Westside Basin Groundwater Model also predicts that the average groundwater flux from the Westside Groundwater Basin to the San Francisco Bay would be 13 afm lower under the cumulative scenario than under the modeled existing conditions (i.e., without any of the cumulative projects). The model predicts that outflow to the San Francisco Bay under the cumulative scenario may vary over the hydrologic period from 4 afm greater than modeled existing conditions to 35 afm lower under cumulative conditions than under modeled existing conditions (Kennedy/Jenks 2012c). This decreased average flux would tend to allow incipient or additional seawater intrusion into the Westside Groundwater Basin.

These decreased flux estimates are not specific to the shallow groundwater zone, but suggest that, generally, more groundwater would flow in from the bay under cumulative conditions than under modeled existing conditions.

Primary Production and Deep Aquifers

At the Burlingame-D monitoring well (located adjacent to the San Francisco Bay in the south Westside Groundwater Basin Primary Production Aquifer), the Westside Basin Groundwater Model results predict that the change in groundwater levels due to the cumulative conditions scenario would range between a rise of 2.2 feet and a drop of 0.7 feet during the 47-year hydrologic sequence. Average groundwater levels at the Burlingame-D monitoring well under the cumulative scenario are predicted to be 1.2 feet higher than the average groundwater levels under modeled existing conditions during the 47-year hydrologic sequence. (Kennedy/Jenks 2012c)

Simulated groundwater levels at the Burlingame-D monitoring well are predicted to be below the exclusion head 100 percent of the hydrologic sequence under the cumulative scenario, which is the same as it is predicted to be under the modeled existing conditions.

The Westside Basin Groundwater Model does not provide data for the South Westside Basin Deep Aquifer. However, the sediments present in the Deep Aquifer are not continuous to the Bay, being separated from it by deposits of low-permeability Bay Mud that likely stretch from the land surface to the bedrock surface below (Kennedy/Jenks 2012c). Therefore, any Deep Aquifer seawater intrusion under the cumulative scenario would need to pass through the Shallow and Primary Production Aquifers before reaching the Deep Aquifer. Because the cumulative projects are not expected to induce seawater intrusion greater than that expected under modeled existing conditions in the Shallow or Primary Production Aquifers, there would be no additional seawater intrusion that could reach the Deep Aquifer.

As indicated by the modeled decrease in average groundwater flux from the Westside Groundwater Basin to the San Francisco Bay, the cumulative scenario may induce seawater intrusion. Therefore, in the South Westside Groundwater Basin, the cumulative scenario is predicted to cause an increased risk of seawater intrusion, which would be a *significant* cumulative impact relative to the potential for seawater intrusion. However, the GSR Project is not predicted to cause decreased average groundwater levels in the South Westside Groundwater Basin adjacent to the San Francisco Bay in excess of those under modeled existing conditions and thereby is not predicted to have a substantial adverse effect on average groundwater flux from the Westside Groundwater Basin to the bay (Kennedy/Jenks 2012c). Therefore, the GSR Project would not have a considerable contribution to the cumulative impact relative to seawater intrusion in the South Westside Groundwater Basin (*less than significant*).

Impact C-HY-5: Operation of the proposed Project could have a cumulatively considerable contribution to cumulative impacts on beneficial uses of surface waters. (Less than Significant with Mitigation)

The geographic scope for the analysis of potential cumulative impacts relative to the water quality of surface water bodies in the study area in the study area is the entire Westside Groundwater Basin as shown on Figure 2-1 (Project Vicinity Map). Table 5.1-3 (Projects Considered for Cumulative Impacts) and their locations are shown on Figure 5.1-3 (Location of Projects Considered in the Cumulative Analysis).

Two cumulative projects, the SFGW Project and the Holy Cross Cemetery Expansion Project (cumulative projects A-1 to A-6 and E, respectively) would increase pumping in the Westside Groundwater Basin, potentially leading to lower groundwater levels. One cumulative project, the Vista Grande Drainage Basin Improvement Project (cumulative project B) would discharge treated stormwater to Lake Merced, which could – in turn – potentially increase groundwater levels near Lake Merced. Each of these cumulative projects, together with the continuation of existing pumping in the Westside Groundwater Basin, have been included in the Westside Basin Groundwater Model and the Lake Merced Lake-level Model, so that groundwater levels are also predicted for the effects from operation of the cumulative projects.

Lake Merced

As discussed above, Daly City's proposed Vista Grande Drainage Basin Improvement Project (cumulative project B) would include the addition of stormwater to Lake Merced. For the purposes of the cumulative analysis, the groundwater model assumes that the Vista Grande Drainage Basin Improvement Project would lower the Lake Merced spillway to an elevation of approximately 9.5 feet City Datum from its current elevation of 13 feet City Datum. The cumulative analysis also assumes that Vista Grande Drainage Canal stormwater flows in excess of 75 cubic feet per second (cfs) that meet applicable water quality criteria would be discharged to Lake Merced as a part of that project, and the total resulting annual additions to Lake Merced would range from 19 to 681 af, and the average annual addition would be 209 afy. In addition, the baseflow[31], in the Vista Grande Drainage Canal would likely be diverted to an onsite engineered wetland for treatment and then discharged to Lake Merced on an ongoing basis. The resulting annual additions to Lake Merced would range from 78 to 277 af, with a long-term average of 220 af. Using these assumptions, the mean lake level would be 7.5 feet City Datum as a result of additions to Lake Merced under the Vista Grande Drainage Basin Improvement Project, without influences from the GSR Project or other potentially cumulative projects (Kennedy/Jenks 2012f).

As shown on Figures 5.16-11 (Simulated Lake Merced Level Changes) and 5.16-12 (Simulated Lake Merced Levels Relative to Modeled Existing Conditions), the estimated cumulative Lake Merced water levels are higher than estimated under the modeled existing conditions for much of the 47-year hydrologic modeling period, largely as a result of the GSR Project and Vista Grande Drainage Basin Improvement Project. However, the estimated lake levels are predicted to be below the modeled existing conditions for years two through eight of the simulation period and after year 32 during the modeled design drought conditions. The estimated cumulative lake levels are also consistently lower than are predicted to occur under the GSR Project alone for the entire simulation period, except for a brief period at the beginning of the simulation. Cumulatively, the estimated mean monthly water level in Lake Merced would be 6.1 feet, and the estimated mean annual range would be 1.6 feet. This cumulative estimated mean monthly lake level is 1.4 feet lower than it would likely be under the Vista Grande Drainage Basin Improvement Project alone, and 3 feet lower than it would likely be under the GSR Project alone (Kennedy/Jenks 2012d).

---

[31] Baseflow is the minimum flow in the Vista Grande Drainage Canal that would be present year-round.

As noted above, the estimated lake levels would be below the modeled existing conditions for years two through eight of the simulation period and after year 32. The estimated cumulative lake levels would be below 1 foot for 13 percent of the simulation period compared to four percent under the modeled existing conditions. The minimum monthly lake level would be -4.9 feet City Datum at the end of the design drought. Therefore, cumulative impacts on Lake Merced water levels could be *significant* because water-level declines below the significance threshold of 0 feet are likely to occur. These water-level declines could cause decreased circulation between lakes and related deterioration of water quality, such as increased eutrophication and decreased dissolved oxygen levels, resulting in *significant* cumulative water quality impacts that could adversely affect the beneficial uses of the lake. The GSR Project's contribution to this impact would be cumulatively considerable, because the lake-level declines due to the Project would likely result in lake levels below 0 feet during, and for a period of time after, the design drought. However, similar to and for the reasons discussed under the analysis for the GSR Project alone, the contribution to this impact would be reduced to a less-than-cumulatively considerable level (*less than significant*) with implementation of Mitigation Measures M-HY-9a (Lake Level Monitoring and Modeling for Lake Merced) and M-HY-9b (Lake Level Management for Lake Merced), because, in accordance with these measures, its implementation would ensure that any lake level declines to below 0 feet as a result of the Project would be avoided due to the required reduction in pumping, the alteration of pumping patterns, and/or the addition of supplemental water. Therefore, with implementation of this measure, the Project would not result in long-term changes in water quality that would affect the potential beneficial use of Lake Merced (*less than significant with mitigation*).

As discussed in Section 5.1, Overview, Section 5.1.6 (Groundwater Modeling Overview), the final design of Daly City's proposed Vista Grande Drainage Improvements Project (cumulative project B) has not been determined. Options under consideration include diverting a broad range of stormwater flows to Lake Merced from the Vista Grande Drainage Canal, ranging from diversion of flows above 35 cfs, or 357 afy, to diversion of flows above 170 cfs, or 66 afy (Daly City 2011). Under this range, the baseflow to Lake Merced from the engineered wetland would range from an average of 203 afy to 233 afy, resulting in total diversions to Lake Merced ranging from 299 afy to 560 afy (Kennedy/Jenks 2012f). The values on either end of the range are within 30 percent of the 429-afy volume used in the cumulative analysis. While the specific option selected for the Vista Grande Drainage Basin Improvement Project could result in a different amount of stormwater discharged to Lake Merced than is considered in the cumulative modeling scenario, the resulting mean lake-level range for each of the Vista Grande options is estimated to be 6.7 to 7.9 feet (Kennedy/Jenks 2012f) compared to 6.3 feet City Datum predicted under the modeled existing conditions. Therefore, any additions to Lake Merced would result in an increase in mean lake levels relative to the modeled existing conditions.

Pine Lake

Under cumulative conditions, in addition to the GSR Project, it is assumed that the SFPUC SFGW Project (cumulative project A-1 through A-6), Holy Cross Cemetery Expansion Project (cumulative project E) and Vista Grande Drainage Basin Improvement Project (cumulative project B) would be implemented.

The estimated average modeled groundwater level in monitoring well LMMW-5S, completed in the deeper portion of the Shallow Aquifer, is 26.5 feet NGVD 29 under cumulative conditions, or 13.7 feet lower than the SFRPD lake elevation of 40.1 feet NGVD 29 and 6.7 feet lower than what is estimated under the modeled existing conditions. Based on this potential decrease in groundwater levels, groundwater outflows from the lake would be increased, and an additional 0.0085 mgd (9.5 afy) would be required from the existing Stern Grove well to maintain Pine Lake at the 40.1 feet NGVD 29 lake level. This represents an increase of 0.0042 mgd (5 afy) over the modeled existing conditions.

While additional groundwater would be required to maintain Pine Lake water levels, the estimated amount of additional groundwater pumping is within the 250-gpm (0.36-mgd) capacity of the Stern Grove well. Further, the Westside Basin Groundwater Model incorporates a sufficient amount of pumping (0.013 mgd [15 afy] under cumulative conditions) to maintain Pine Lake at an elevation of 40.1 feet NGVD 29. Therefore, the lake would be maintained at similar levels to those under the modeled existing conditions without adverse effects on the Shallow Aquifer, and maintenance of the lake at this level would not result in any changes to water quality or the health of the lake. Therefore, cumulative water quality impacts on Pine Lake water levels would be *less than significant* (*less than significant*).

Impact C-HY-6: Operation of the proposed Project would not result in a cumulatively considerable contribution to cumulative impacts related to water quality standards. (Less than Significant)

The geographic scope for the analysis of potential cumulative impacts relative to water quality standards in the study are is the entire Westside Groundwater Basin as shown in Figure 2-1 (Project Vicinity Map). Cumulative projects are listed in Table 5.1-3 (Projects Considered for Cumulative Impacts) and their locations are shown on Figure 5.1-3 (Location of Projects Considered in the Cumulative Analysis).

Two cumulative projects, the SFGW Project (cumulative project A-1 to A-6) and the Holy Cross Cemetery Expansion Project (cumulative project E), would increase pumping in the Westside Groundwater Basin, potentially leading to lower groundwater levels. One cumulative project, the Vista Grande Drainage Improvements Project (cumulative project B), would discharge treated stormwater to Lake Merced, which could – in turn – potentially increase groundwater levels near Lake Merced. Each of these cumulative projects, together with the continuation of existing pumping in the Westside Groundwater Basin, have been included in the Westside Basin Groundwater Model so that estimated future groundwater levels are predicted for the effects from operation of the cumulative projects.

The results of the Westside Basin Groundwater Model cumulative conditions scenario predict that groundwater levels in the South Westside Groundwater Basin would be similar to those of the GSR Project scenario. The Model results also predict that the overall effect of the SFGW Project on the South Westside Groundwater Basin would be minimal.

Model-simulated groundwater levels for the cumulative conditions scenario south of Lake Merced and near Daly City primarily show the effects of the GSR Project, with slightly lower groundwater levels than the GSR Project alone due to the combined pumping effects of the cumulative conditions scenario (including the GSR Project). This difference is attributed to the SFGW Project extracting and intercepting groundwater that would otherwise flow from the North Westside Groundwater Basin south into the Daly City area. Groundwater levels in the cumulative simulation mimic the trends seen in the modeled simulation of the GSR Project in the remainder of the South Westside Groundwater Basin. Near South San Francisco and San Bruno, the effects of the SFGW Project would be minimal due to the intervening distance; the groundwater levels under the cumulative scenario reflect conditions similar to the GSR Project impacts. (Kennedy/Jenks 2012e).

Because groundwater level impacts from the cumulative projects would be similar to the groundwater level impacts for the GSR Project alone, potential cumulative impacts related to water quality standards would be *less than significant* for the same reasons that the GSR Project-specific impacts would be less than significant. As summarized in Impact HY-12 above, contaminants reported at PCA sites in soil or in shallow or perched groundwater zones are not anticipated to be mobilized during well pumping. This conclusion is based on the reported shallow nature of contamination at the PCAs and the aggregate thicknesses of intervening clay and sand layers between the shallower parts of the aquifer and the Primary Production aquifer from which the GSR Project would pump (see analysis of Impact HY-12). Therefore, the potential impact on drinking water standards from mobilization and spreading of contaminants in groundwater, changes in flow direction, or changes to operating conditions for remediation systems as a result of cumulative pumping would be *less than significant*. Consequently, there would be no such significant cumulative impact to which the GSR Project would contribute (*less than significant*).

Impact C-HY-7: Operation of the proposed Project would not result in a cumulatively considerable contribution to cumulative impacts related to water quality degradation. (Less than Significant)

The geographic scope for the analysis of potential cumulative impacts on water quality degradation in the study area is the entire Westside Groundwater Basin as shown in Figure 2-1 (Project Vicinity Map). Table 5.1-3 (Projects Considered for Cumulative Impacts) and their locations are shown on Figure 5.1-3 (Location of Projects Considered in the Cumulative Analysis).

Two cumulative projects, the SFGW Project (cumulative project A-1 to A-6) and the Holy Cross Cemetery Expansion Project (cumulative project E), would increase pumping in the Westside Groundwater Basin, potentially leading to lower groundwater levels. One cumulative project, the Vista Grande Drainage Basin Improvement Project (cumulative project B), would discharge treated stormwater to Lake Merced, which could – in turn – potentially increase groundwater levels near Lake Merced.

Increased pumping in the Westside Groundwater Basin by the SFGW Project and the Holy Cross Cemetery Expansion Project could potentially encounter very low levels of chemicals for which no regulatory standards exist, just as the proposed GSR Project monitoring wells have (see the discussion of Impact HY-14, above). However, groundwater quality monitoring by the SFPUC, Partner Agencies, and the GAMA program throughout the Westside Groundwater Basin indicates that groundwater quality in the Basin is generally very good. The SFPUC's monitoring program has identified VOCs in the Primary Production and Deep Aquifers in the Westside Groundwater Basin (Kennedy/Jenks 2012e). The GAMA groundwater quality monitoring program (described above under Water Quality Standards) sampled 11 wells within the Westside Groundwater Basin. Pesticides, pharmaceutical compounds, and wastewater indicator compounds – including those for which no regulatory standards have been established – were not detected in any of the 11 wells within the Westside Groundwater Basin (Ray et al. 2009).

Therefore, increased pumping in the Westside Groundwater Basin due to the cumulative projects is not likely to encounter chemicals in groundwater that would present substantial health risks.

The Vista Grande Drainage Improvements Project would potentially degrade the water quality in Lake Merced, if untreated stormwater were discharged to the Lake. However, groundwater quality below

Lake Merced would not be substantially affected by such discharges due to percolation of lake water through sediment, soils, and geological formations before reaching the aquifer, which has the effect of filtering the stormwater before it reaches the groundwater. As a result, these cumulative projects would not cause significant degradation of groundwater quality in the Westside Groundwater Basin. Therefore, potential cumulative impacts relative to the degradation of drinking water quality or groundwater quality for constituents for which standards do not exist would be *less than significant*. Consequently, there would be no such significant cumulative impact to which the GSR Project would contribute (*less than significant*).

Impact C-HY-8: Operation of the proposed Project would have a cumulatively considerable contribution to a cumulative impact related to groundwater depletion effect. (Less than Significant with Mitigation)

The geographic scope for the analysis of potential cumulative impacts relative to groundwater depletion in the study area is the entire Westside Groundwater Basin is shown in Figure 2-1 (Project Vicinity Map). Table 5.1-3 (Projects Considered for Cumulative Impacts) and their locations are shown on Figure 5.1-3 (Location of Projects Considered in the Cumulative Analysis).

Two cumulative projects, the SFGW Project (cumulative project A-1 to A-6) and the Holy Cross Cemetery Expansion Project (cumulative project E), would increase pumping in the Westside Groundwater Basin and potentially lead to less groundwater storage. One cumulative project, the Vista Grande Drainage Basin Improvement Project (cumulative project B), would discharge treated stormwater to Lake Merced, which could – in turn – potentially increase groundwater storage near Lake Merced. Each of these cumulative projects, together with the continuation of existing pumping in the Westside Groundwater Basin, have been included in the Westside Basin Groundwater Model (described in Kennedy/Jenks 2012a), so that future predicted groundwater volumes for the cumulative conditions scenario include the effects from operation of the cumulative projects.

Groundwater storage under the cumulative scenario is estimated to be less than estimated groundwater storage under the modeled existing conditions; the projected decline is predicted to be approximately 970 afy, which would represent a decline in storage over the 47-year simulation period of approximately 45,000 af more than under the modeled existing conditions. This change in groundwater storage represents about 4.2 percent of the total groundwater volume in the entire onshore portion of the Westside Basin. Even though this decline is small, the results of the Westside Basin Groundwater Model regarding groundwater storage volumes for the cumulative condition indicate an incremental depletion of groundwater storage over the long-term, which is a *significant* cumulative impact. The GSR Project's contribution to this impact would be cumulatively considerable, because the groundwater storage volume would decline due to the Project. However, similar to and for the reasons discussed in the analysis for the GSR Project alone, the contribution to this impact would be reduced to a less-than-cumulatively considerable level (*less than significant*) with implementation of Mitigation Measure M-HY-14 (Prevent Groundwater Depletion), because additional in-lieu recharge would be allowed, and Project pumping would be restricted to extract only the volume of water in the SFPUC Storage Account, which would be adjusted to account for Basin losses. Therefore, with implementation of this measure, the Project would not result in a considerable contribution to any potential long-term cumulative depletion of groundwater storage (*less than significant with mitigation*).

5.16.3.9 Impacts of Mitigation Measures

Well Interference

This section provides an evaluation of whether there would be any significant impacts in addition to those identified for the Project due to implementation of Mitigation Measure M-HY-6 (Ensure Existing Irrigators' Wells Are Not Prevented from Supporting Existing or Planned Land Use Due to Project Operation). This mitigation measure lists a number of mitigation actions that may be undertaken by the SFPUC to meet the performance standard established in the mitigation measure. Nine mitigation actions are listed in the mitigation measure as examples of the types of actions that could result in a reduction of impacts from well interference, as follows:

1. Improve irrigation efficiency
2. Modify irrigation operation
3. Redistribute GSR pumping
4. Reduce GSR pumping
5. Lower pump in irrigation well
6. Lower and change pump in irrigation well
7. Add storage capacity for irrigation supply
8. Replace irrigation well
9. Replace irrigation water source

These nine mitigation actions are described below in detail; mitigation actions with similar effects are discussed together.

M-HY-6 Mitigation Action #1: Improve Irrigation Efficiency, and Mitigation Action #2: Modify Irrigation Operations

M-HY-6 Actions #1 and #2 could improve irrigation efficiency and reduce water needs if irrigation pumping is anticipated to decline as a result of Project pumping. Conservation practices would be designed to help control water losses due to evaporation, deep percolation, and runoff. The measures could result in changes to the irrigation schedule (i.e. use of longer irrigation cycles or use of evapotranspiration data to modify irrigation schedules), which may lead to changes to the irrigation timing and amount of water applied to the golf clubs and cemeteries to improve water application efficiency while satisfying turfgrass water needs. Minor physical modifications could include replacing sprinkler nozzles, replacement and/or additional sprinklers to redistribute irrigation more evenly, or installation of soil-moisture sensors to aid irrigation scheduling. (SFPUC 2012c)

M-HY-6 Mitigation Action #3: Redistribute GSR Pumping

M-HY-6 Action #3 would keep the overall Project pumping at up to 7.2 mgd during a Take Year, but redistribute Project pumping so that Project wells that were causing well interference with an existing irrigator's well would be pumped less, and other Project wells that were demonstrating less drawdown than predicted by the groundwater modeling would be pumped more. Pumping would be redistributed only if there are GSR wells where groundwater levels are higher than predicted. This mitigation action would not require any construction, but could temporarily and/or occasionally change the pumping rate at one or more of the Project wells. (SFPUC 2012c)

M-HY-6 Mitigation Action #4: Reduce GSR Pumping

M-HY-6 Action #4 would reduce Project pumping. Reduced pumping would not require any construction or operational changes, and therefore no construction or operational impacts would occur due to reduced pumping.

M-HY-6 Mitigation Action #5: Lower Pump in Irrigation Well and Mitigation Action #6: Lower and Change Pump in Irrigation Well

If needed as a mitigation action, the existing irrigation pump affected by Project pumping would be modified to allow irrigation pumping to continue. The modification would include lowering the pump deeper in the existing well and may include a change in the size and characteristics of the pump to accommodate pumping from deeper water levels. (SFPUC 2012c)

M-HY-6 Mitigation Action #7: Add Storage Capacity for Irrigation Supply

If needed as a mitigation action, storage capacity to meet peak flow rates required for irrigation purposes may be added to offset reduced well capacity caused by Project pumping. Additional storage capacity could be added through installation of an above-ground storage tank with a capacity of 20,000 gallons or less, which could be up to 20 feet in height, and sized according to the peak flow needs. The tank would be painted to blend in with the surrounding area (SFPUC 2012c) (i.e., green for vegetative surroundings). It is assumed, for purposes of this analysis, that the storage would be located adjacent to the existing well that would be impacted by Project pumping and that the storage facility would connect directly to the existing irrigation system infrastructure. To install a typical tank, a site would be cleared and graded as needed to prepare the site. Depending on the size of the tank needed to supply the peak flow water quantities, either a tank may be constructed on the site or a pre-fabricated tank moved to the site. A concrete foundation may be required depending upon the type and size of the tank and the site characteristics. Equipment used for tank construction could include a bulldozer for earthwork and grading, crane, concrete trucks, delivery trucks, and roller compaction equipment. After construction is completed, the area around the new tank disturbed by its installation would be restored to its general pre-construction condition. (SFPUC 2012c)

M-HY-6 Mitigation Action #8: Replace Irrigation Well

If needed as a mitigation action, a replacement well at a cemetery or golf club could be constructed on the cemetery or golf club property. This analysis assumes that the irrigation well would be sited to avoid impacts on: waters of the United States or of the State of California; wetlands; other sensitive habitat; or cultural and historic resources. It also assumes that the new irrigation well would not be sited directly on land currently used for agriculture, or land that has a unique geologic feature, but it could be sited adjacent to such land.

To install a typical replacement well, a site would first be cleared and graded (as needed). A steel conductor casing would be installed to a minimum depth of 50 feet. A large diameter borehole would be drilled to a depth of approximately 550 to 700 feet. The well casing, consisting of a steel well casing and well screen, would be installed in the production borehole. After the well casing has been installed, well development would begin. Various well pumping tests would be performed after final well development. If the pumping test shows that water quality and production would meet the need of the landowner, then a pump, valves, flowmeter, and electrical connection would be installed. Equipment used for replacement well construction would likely include a truck-mounted drill rig, shale shaker, drilling fluid tanks, support trucks, Baker Tanks, forklift, and loader/backhoe. Approximately 45 working days would be required for well construction, development, and testing. After construction, the construction work area would be restored to its general pre-construction condition, including any golf course playing surfaces or other landscaping. (SFPUC 2012c)

M-HY-6 Mitigation Action #9: Replace Irrigation Water Source

In the event that the preceding options cannot be immediately implemented without causing an interruption in the irrigation supply, a temporary replacement water supply source would be provided until another mitigation option(s) is implemented. Water would be trucked to the site or would be provided via aboveground pipes from Partner Agency or SFPUC supply from distribution or transmission pipelines close to the location where additional irrigation supplies are needed. The SFPUC would verify that the water quality of the new irrigation source is acceptable. (SFPUC 2012c)

The effects of these mitigation actions are evaluated together under each environmental resource area. For the following three resource areas, none of the mitigation actions would result in additional impacts:

- **Population and Housing**. Implementation of M-HY-6 Actions #1 through #9 would not result in impacts related to population and housing, because these actions would not increase or displace existing population and do not include the construction of new, or displacement of existing, housing. Therefore, there would be no additional impact on the environment relative to the construction of new housing.
- **Wind and Shadow**. M-HY-6 Actions #1 through #6, and #8 and #9 do not include construction of new structures that could alter wind and shadow patterns. Action #7 includes the placement of a new storage tank, up to 20 feet tall, next to an existing irrigation well. The size of the storage tank would not be substantial enough to alter wind patterns or significantly alter shadow patterns such that enjoyment or use of the golf clubs or cemeteries would be affected. Therefore, there would be no additional impacts related to wind and shadow.
- **Public Services**. Implementation of M-HY-6 Actions #1 through #9 would not result in impacts related to public services because these actions would not increase population in the study area and therefore would not affect the ability of local jurisdictions to maintain service ratios, response times, or other performance objectives. Therefore, there would be no additional impact on the environment relative to public services.

The potential effects of the nine mitigation actions on the remaining resource areas are discussed below.

Land Use

Implementation of M-HY-6 Actions #1 through #4 would not result in impacts on land use, because these actions would not generate construction- or operation-related noise, dust, or exhaust emissions, and would not include construction equipment or permanent structures that would adversely affect the existing character of the land use. *No impact* would occur for M-HY-6 Actions #1 through #4.

While M-HY-6 Actions #5, #6, and #9 would require the use of construction equipment and vehicles, the scope of these construction activities would be similar to ongoing maintenance activities at the golf clubs and cemeteries. Therefore, construction impacts for M-HY-6 Actions #5, #6, and #9 would be *less than significant*. Depending on the placement of the pipelines, operation of M-HY-6 Action #9 may result in minor disruption to recreational uses at the golf clubs. The temporary placement of aboveground pipelines in golf clubs could result in golf carts needing to maneuver around pipelines while traveling within the golf club; however, aboveground pipelines would be placed and operated such that the golf club would remain available and useable to golfers. The temporary operational impacts of M-HY-6 Action #9 would not displace the land use and would therefore be *less than significant*.

M-HY-6 Actions #7 and #8 could result in temporary adverse impacts on land use due to substantial disruption of existing land uses or substantial interference with access to land uses during construction from the combination of temporary increases in noise and dust/exhaust emissions levels, traffic delays, and/or access disruption. Depending on the location of the storage tank or new well (i.e., whether visible from a publicly accessible vantage point), implementation of this mitigation action could temporarily degrade the visual quality of the site or scenic views during construction, and therefore temporarily affect the existing character of surrounding land uses. Therefore, these potential impacts could be *significant*. Implementation of Mitigation Measures M-NO-1 (Noise Control Plan), M-AQ-2a (BAAQMD Basic Construction Measures), M-TR-1 (Traffic Control Plan), and M-AE-1a (Site Maintenance) to reduce Project impacts would also reduce impacts from construction activities related to M-HY-6 Action #7 and #8 to *less-than-significant* levels by requiring measures to reduce construction-related noise, dust, emissions, and traffic access-related issues to *less-than-significant* levels It is unlikely that the wells would displace existing land uses because the new wells could be located at the same site as the existing wells, and no perceptible noise would be generated from the wells; therefore, there would be *no operational impacts* on existing land uses from M-HY-6 Action #8. Given the size of the properties involved and their open-space nature, this analysis assumes that a new storage tank could be sited in an area that would not conflict with existing land use where this mitigation might be required, even though the possible locations for a new tank have not been identified for each irrigator. Therefore, the potential land use impact associated with implementation of M-HY-6 Action #7 is assumed to be *less than significant*.

Aesthetics

Implementation of M-HY-6 Actions #1 through #4 would not result in additional impacts on visual resources, because these actions would not involve construction activities or new aboveground structures that would alter or impact the visual quality of the cemeteries or golf clubs as viewed from publicly accessible vantage points. Additionally, the purpose of these mitigation actions is to ensure continued adequate water for irrigation at the golf clubs or cemeteries, therefore the operation of these facilities would not be impacted by these mitigation actions. As a result, *no construction or operational impacts* related to aesthetics would occur for M-HY-6 Actions #1 through #4.

The implementation of M-HY-6 Actions #5 through #9 could result in minor additional aesthetic impacts during construction due to the presence of construction equipment and vehicles; these impacts could be *significant* if construction sites were visible from publicly accessible viewpoints. Implementation of

Mitigation Measures M-AE-1a (Site Maintenance) would reduce construction impacts to *less-than-significant* levels by keeping the area clean of debris. Construction-related aesthetic impacts from implementation of M-HY-6 Actions #5 through #9 would therefore be *less than significant with mitigation*.

M-HY-6 Actions #5 and #6 would not have operational impacts related to aesthetics, because they would not include any aboveground changes, therefore *no operational impact* would occur for Actions #5 and #6. However, M-HY-6 Actions #7 and #8 could result in additional aesthetic impacts during operation. Placement of a storage tank up to 20 feet tall (M-HY-6 Action #7) could affect the visual quality and character of the golf club or cemetery, however, SFPUC would work with the landowner to site the tank in a location that minimizes visual impacts from publicly accessible viewpoints. Certain factors such as the tank's proximity to other structures or the presence of natural screening (i.e., trees or topography) could limit impacts on the visual character of the site or its surroundings. Additionally, the storage tank would be painted to blend in with its surroundings (SFPUC 2012c) (i.e., green for areas with evergreen turf or vegetation). If significant aesthetic impacts would still result from the installation of a new water tank, per this measure, this analysis assumes that Mitigation Measure M-AE-3a (Implement Landscape Screening) could also be implemented, as necessary, to mitigate such impacts to *less-than-significant* levels. This would be accomplished by requiring the SFPUC to develop and implement a landscape screening plan to screen publicly accessible views of the new water storage tank(s), including the following:

- The landscape plan shall include native trees and shrubs common to the surrounding areas. The landscape plan shall include plant species, planting specifications, and irrigation requirements necessary to screen the new water storage tank(s). The SFPUC shall monitor landscape plantings annually for five years after project completion to ensure that sufficient ground coverage has developed and that the shrubs survive. If necessary, the SFPUC shall implement additional measures (e.g., replanting, temporary irrigation) to address continued survival of the plantings, and shall replant additional shrubs should a significant amount of the plantings do not survive during the monitoring period.

M-HY-6 Action #8 would construct a replacement irrigation well at a golf club or cemetery. However, the aesthetic impact of the well would be minor, because the well would extend approximately three feet above ground, which would not significantly affect viewsheds or the visual quality of the cemetery or golf clubs, as viewed from publicly accessible vantage points. M-HY-6 Action #9 would potentially affect the visual quality of the cemetery or golf club because the pipelines would be located above ground. However, this mitigation action is intended to be temporary in duration. For these reasons, operational impacts on aesthetics from M-HY-6 Actions #8 and #9 would be *less than significant*.

Cultural and Paleontological Resources

Implementation of M-HY-6 Actions #1, #2, #3, #4 #5, #6, and #9, would not result in additional impacts on cultural or paleontological resources, because these actions would not involve additional excavation, grading, or other ground disturbances. Implementation of these mitigation actions would also not involve new structures or changes to historical resources. As a result, *no impacts* would occur.

There are no historical resources identified at the golf clubs that could be affected by the Project, but several cemeteries within the study area include individual historic resources or the cemeteries are eligible for listing on the National Register. If historic resources are present at a golf club or cemetery where a storage tank or replacement well (M-HY-6 Actions #7 and #8) might be needed, the facilities would be sited to avoid impacts on these resources (i.e., sited where the storage tank and well are not visible in proximity to a historic resource), where feasible. Construction of the storage tank or well would be short in duration and impacts on the historic resources during construction would therefore be *less than significant*. Once in place, if a storage tank is within close proximity of a historic resource, the implementation of Mitigation Measures M-AE-3a (Implement Landscape Screening) would reduce impacts on historic resources by providing screening, as also described above to address any potential aesthetics impacts.

It is unknown whether M-HY-6 Action #7 or #8 would be implemented at a site that contains archaeological or paleontological resources. Damage to an archaeological or paleontological resource would be a *significant* impact. However, implementation of Mitigation Measures M-CR-2 (Discovery of Archaeological Resources), M-CR-3 (Suspend Construction Work if a Paleontological Resource is Identified), and M-CR-4 (Accidental Discovery of Human Remains) would adequately address any potential impacts related to the accidental discovery of these resources during construction by requiring adherence to appropriate procedures and protocols. Impacts on cultural and paleontological resources as a result of implementing M-HY-6 Action #7 or #8 would therefore be *less than significant with mitigation*.

Transportation and Circulation

Implementation of M-HY-6 Actions #1 through #4 would not impact transportation and circulation because no construction would be required, and therefore *no construction traffic impacts* would occur. Because these actions would not require additional maintenance vehicle trips, operation would not permanently impact the performance of the transportation circulation system or increase traffic hazards and *no operational impact* would occur.

Implementation of M-HY-6 Actions #5, #6, #7, #8, or #9 could result in additional impacts on transportation and circulation due to additional construction traffic on regional highways and local roadways. However, construction traffic from these mitigation actions would be minor and temporary (i.e., truck deliveries for well pump, storage tank, or piping). Because any storage tanks, replacement wells or irrigation piping would be located on existing golf club or cemetery property and connected to onsite irrigation plumbing (rather than periodically filled by delivery truck), implementation of M-HY-6 Actions #7, #8, or #9 would not permanently impact the performance of the transportation circulation system or increase traffic hazards. Therefore, operational impacts of M-HY-6 Actions #5, #6, #7, #8, or #9 would be *less than significant*.

Noise and Vibration

Implementation of M-HY-6 Actions #1 through #4 would not result in construction or operational noise impacts because these actions would not include construction activities or result in new sources of noise. *No noise or vibration impacts* would therefore occur.

Implementation of M-HY-6 Action #5, #6, and #9 would not generate significant noise impacts during construction. Lowering and/or replacing the pump, or installing aboveground pipelines would be similar in nature to other ongoing maintenance activities and would not substantially increase ambient noise levels at the golf clubs or cemeteries. Any related noise impacts would therefore be *less than significant*. *No* *operational impacts would occur*, because the changed pump and aboveground pipelines would not generate perceptible changes in ambient noise levels.

Implementation of M-HY-6 Action #7 would result in additional noise and vibration impacts during construction due to site grading and clearing, construction of a concrete foundation (if necessary), and the use of construction equipment and vehicles. Implementation of M-HY-6 Action #8 would also result in additional noise and vibration impacts during construction of the replacement irrigation well. If pipelines are required for the irrigation well, pipeline trench compaction during construction could cause ground-borne vibration, which would be potentially significant depending on the proximity to structures and sensitive receptors. While golf clubs are not considered sensitive noise receptors, cemeteries and places of residence, schools, and churches are considered sensitive to noise disturbances. Additionally, Daly City, Colma, and San Bruno have specific noise regulations for cemeteries and/or golf clubs. Construction of M-HY-6 Actions #7 or #8 could exceed local noise standards and temporarily increases ambient noise levels, which would be *significant*.

Mitigation Measures M-NO-1 (Noise Control Plan) would reduce construction-related noise impacts for M-HY-6 Actions #7 and #8. Mitigation Measure M-NO-2 (Reduce Vibration Levels during Construction of Pipelines) would reduce noise and vibration levels generated during well drilling and pipeline trench compaction. Implementation of M-NO-1 (Noise Control Plan) would reduce noise impacts from Action #7 to *less-than-significant* levels. However, Action #8 includes drilling, and as discussed in Section 5.7, Noise and Vibration, depending on the proximity of construction to a sensitive noise receptor (e.g., residences or schools), and depending on the local noise regulations for cemeteries and/or golf clubs, it is possible that even with the implementation of these mitigation measures, noise impacts related to noise standards and ambient noise levels from well drilling could be *significant and unavoidable*.

Operation of the storage tank (M-HY-6 Action #7) would not increase ambient noise levels at the golf clubs or cemeteries. Operation of the irrigation well (M-HY-6 Action #8) would not increase ambient noise levels because the pump would be located underground. *No operational noise impacts* would therefore occur.

Air Quality

Implementation of M-HY-6 Actions #1 through #4 would not require construction, and therefore would not result in the emission of criteria air pollutants or violation of air quality standards. *No impact* would occur. M-HY-6 Actions #5, 6, and #9 would require use of construction equipment and vehicles (but no ground disturbance), and would generate small amounts of exhaust emissions. M-HY-6 Actions # 7 and #8 would generate fugitive dust and other criteria air pollutants from construction activities such as grading and excavation, and the use of construction equipment and vehicles. These emissions could be *significant*. However, implementation of M-AQ-2a (BAAQMD Basic Construction Measures) would reduce impacts to *less-than-significant* levels by requiring measures to control dust and reduce idling. Post-construction, these mitigation actions would not emit criteria air pollutants. *No impact* from operations would therefore occur.

Greenhouse Gas (GHG) Emissions

Implementation of M-HY-6 Actions #1 through #4 would not require construction, and therefore would not generate greenhouse gases. *No impact* would occur. M-HY-6 Actions #5, 6, #7, #8, and #9 would generate a small additional amount of GHG emissions through the combustion of fossil fuels in mobile construction equipment and vehicles, and from the purchase of electricity to operate any electrical equipment for Project construction. However, due to the small scale of these mitigation actions, GHG emissions generated during construction would be *less than significant*. Operation of the Actions #5, #6, #7, and #9 would be similar in scope to existing maintenance activities. Action #8 would replace an existing well, so maintenance activities would be the same as for the existing well, and would not result in additional GHG emissions. Therefore, operational impacts associated with GHG emissions generated from worker trips and energy use would be *less than significant*.

Recreation

Implementation of M-HY-6 Actions #1 through #4 would not require construction. Operation of these mitigation actions would facilitate the continued recreational function of the golf clubs by providing irrigation water. *No impact* would therefore occur.

M-HY-6 Actions #5 and #6 would require the use of construction equipment and vehicles, and construction would be similar to ongoing maintenance activities at the golf clubs, because no ground disturbance would occur and significant noise or dust would not be generated. Therefore, impacts on recreational experience would be *less than significant*. No permanent changes to the recreational facilities would occur, so *no operational impacts* would occur.

Implementation of M-HY-6 Actions #7, #8, and #9 could result in additional impacts on recreation during construction. If M-HY-6 Action #7 is implemented at a golf club, the storage tank would likely be located immediately adjacent to the affected existing irrigation well. If M-HY-6 Action #8 is implemented at a golf club, the replacement irrigation well would likely be sited at the outer fringes of playing surfaces or in other non-playing areas, to minimize damage to playing surfaces. Implementation of M-HY-6 Action #9 could result in temporary impacts at golf clubs. Placement of aboveground pipelines could temporarily affect golf cart access between holes and may require golfers using golf carts to take alternative access routes if pipelines cross internal golf club roadways; otherwise pipeline placement would not prevent golfers from using the golf club or impact playing surfaces. Therefore, it is unlikely that the placement of the storage tank, irrigation well, or aboveground pipelines would substantially damage or displace existing playing surfaces.

Construction of these mitigation actions could temporarily affect the quality of the recreational experience or temporarily affect golf cart access within the golf club; these temporary impacts on recreational experience would be *less than significant* because disruption would be limited and short-term (typically less than one month), and because other recreational resources are available in the area.

Any golf club playing surfaces damaged during construction would be restored to their general pre-construction condition after construction is completed (pursuant to Chapter 3, Project Description, Section 3.5.1.3 [Construction Methods for Water Distribution and Utility Pipeline Installation], which specifies that areas disturbed during construction would be restored to pre-construction conditions). As stated earlier, it is unlikely that the storage tank or irrigation well would substantially displace existing playing surfaces. Depending on the placement of the pipelines, operation of M-HY-6 Action #9 may result in temporary and minor disruption of recreational uses at the golf clubs. Implementation of these actions would not result in population growth, and therefore would not increase the use, or require the expansion of existing parks or recreational facilities. Therefore, operational recreation impacts of M-HY-6 Actions #7, #8, and #9 would be *less than significant*.

Utilities and Service Systems

Implementation of M-HY-6 Action #1, #2, #3, #4, #5, #6, and #9 would not require trenching or other ground disturbances that could disrupt or damage existing utilities. These mitigation actions would not require additional water entitlements; generate additional solid waste or additional discharges to sanitary sewer or stormwater systems. *No such impacts* would therefore occur.

Implementation of M-HY-6 Actions #7 and #8 would result in additional potentially *significant* impacts on utilities and service systems by contributing small additions of solid waste generated during construction and potentially damaging or disrupting utilities during construction. However, as discussed in Section 5.12, Utilities and Service Systems, the Ox Mountain Landfill has a remaining capacity that is sufficient to accommodate the amount of solid waste that would be generated by implementation of M-HY-6 Actions #7 and #8. Additionally, Mitigation Measure M-UT-4 (Waste Management Plan) would require compliance with local solid-waste diversion goals and regulations. Implementation of Mitigation Measures M-UT-1a (Confirm Utility Line Information), M-UT-1b (Safeguard Employees from Potential Accidents Related to Underground Utilities), M-UT-1c (Notify Local Fire Departments), M-UT-1d (Emergency Response Plan), M-UT-1e (Advance Notification), M-UT-1f (Protection of Other Utilities during Construction), M-UT-1g (Ensure Prompt Reconnection of Utilities), M-UT-1h (Avoidance of Utilities Constructed or Modified by Other SFPUC Projects), and M-UT-1i (Coordinate Final Construction Plans with Affected Utilities) would adequately address impacts related to the potential disruption and relocation of utility operations or accidental damage to existing utilities by requiring the SFPUC and/or its contractor(s) to identify the potentially affected lines in advance, coordinate with utility service providers to minimize the risk of damage to existing utility lines, protect lines in place to the extent possible or temporarily re-route lines if necessary, and take special precautions when working near high priority utility lines (e.g., gas transmission lines). Construction impacts on utilities and service systems from M-HY-6 Actions #7, and #8 would therefore be *less than significant with mitigation*. Construction of M-HY-6 Action #8 would also discharge to the local sanitary sewer or storm drain system during well development pumping tests. However, as described in Section 5.12, Utilities and Service Systems, the sanitary sewer and storm drain systems in the Project area have sufficient capacity to handle the volume and rate of such discharges during well development.

Operation of M-HY-6 Actions #7 and #8 would not result in impacts on utilities or service systems. A new storage tank would not result in additional discharges to the storm drain or sanitary sewer system. Since Action #8 involves replacing an existing well, no additional discharges to the storm drain or sanitary sewer system would occur.

Biological Resources

Implementation of M-HY-6 Actions #1 through #4, and #9 would occur on existing golf club or cemetery property and would not modify existing habitats or require tree removal. Implementation of M-HY-6 Action #5 or #6 would not impact biological resources, because these actions would not require additional construction activities beyond lowering and/or changing the well pump. No trees would be removed and no surface ground disturbance would occur. Construction equipment and workers would be present, but would avoid any waters of the State or of the United States, wetlands, or sensitive habitat near or adjacent to the construction site, as discussed previously in the mitigation action descriptions. As a result, *no impacts* on biological resources from M-HY-6 Actions #1 through #6, and #9 would occur.

Implementation of M-HY-6 Actions #7 and #8 could result in additional potentially *significant* impacts on biological resources. Storage tanks would likely be located adjacent to existing irrigation wells. Storage tanks and replacement irrigation wells would be sited to avoid jurisdictional waters, wetlands, or other sensitive habitat. However, implementation of this mitigation action could potentially require the removal of trees to accommodate placement of a new tank depending on where the tank was constructed. Implementation of Mitigation Measures M-BR-1a (Protection Measures during Construction for Special-status Birds and Migratory Passerines and Raptors), M-BR-1b (Protection Measures for Special-status Bats during Tree Removal or Trimming), M-HY-1 (Develop and Implement a Stormwater Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan), M-BR-4a (Identify Protected Trees), and M-BR-4b (Protected Tree Replacement) would reduce any such potential impacts to l*ess-than-significant* levels. These measures would require pre-construction surveys to determine whether special-status or migratory birds or bats (including their nests and roosts), or overwintering monarch butterflies are present at or near construction sites. These also include measures to protect nearby habitat from construction-related runoff and sedimentation, and require trees to be protected, avoided, and replaced in accordance with local tree protection ordinances if removed. Therefore, impacts on biological resources from M-HY-6 Actions #7 and #8 would be *less than significant with mitigation*.

Geology and Soils

Implementation of M-HY-6 Actions #1 through #6, and #9 would occur on existing golf club or cemetery property and would not include the construction of new structures that could expose people to seismic ground shaking or landslides. Implementation of Actions #1, #2, #5, #6, and #9 would be similar in nature to existing ongoing maintenance activities; Actions #3 and #4 would not result in physical changes, and therefore would not result in new or increased risk for landslides or other soil or geologic instability risks. As a result, *no impacts* would occur.

M-HY-6 Action #7 could potentially place a storage tank on unstable soil that could be susceptible to landslides, ground shaking, or settlement. The exposure of this structure to potentially adverse seismic effects that could lead to tank failure could be *significant*. However, implementation of Mitigation Measure M-GE-3 (Conduct Site-specific Geotechnical Investigations and Implement Recommendations) would require site-specific geotechnical investigations, and implementation of recommendations to protect against property loss, injury, or death from ground shaking or settlement that could result from the damage of a new water tank and would be reduced to *less-than-significant* levels. Installation and operation of a replacement irrigation well identified in M-HY-6 Action #8 would not include construction of structures intended for human occupancy; therefore, there would be no exposure of people or structures to the effects of landslides, ground shaking, or settlement.

Given that any storage tanks or replacement irrigation wells would be located within existing cemeteries or golf clubs, which are carefully landscaped and highly disturbed, it is unlikely that implementation of these mitigation actions would substantially change existing topography or unique geologic or physical features. If a replacement well were to be sited on the Holy Cross Cemetery property east of Hillside Boulevard, the well would likely be sited to avoid substantial changes to existing topography or unique geologic or physical features. Such potential impacts would be *less than significant*.

Hydrology and Water Quality

Implementation of the M-HY-6 Actions #1, #2, #4 #5, #6 and #9 would not include ground-disturbing construction activities and therefore these mitigation actions would not result in erosion or runoff that would impact water quality. Irrigation (Actions #1, #2, and #9) would follow standards necessary to reduce runoff to surface waters and percolation to groundwater. If a new well is drilled (Action #8), SFPUC would ensure that water quality of the new well is appropriate for irrigation use. Actions #5 and #6 would modify pumping to allow irrigation pumping to continue at existing levels. Action #4 would reduce Project pumping and not require any other construction or operational changes. Therefore, there would be *no impacts* on hydrology or water quality from these mitigation actions.

Implementation of M-HY-6 Actions #7 and #8 could require vegetation removal, grading, excavation, and soil stockpiling, which could result in erosion and sedimentation and impact water quality. This would be a *significant* impact. However, implementation of Mitigation Measure HY-1 (Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan), would reduce such potential impacts to *less-than-significant* levels by requiring stabilization and control measures during ground disturbing activities.

Redistribution of pumping under M-HY-6 Action #3 would not have the potential for additional well interference, subsidence, seawater intrusion, or Lake Merced water quality impacts, because Mitigation Measure M-HY-6 specifies that redistribution of pumping would not occur in a manner that would cause groundwater levels to drop below that caused by the Project.

If pumping were redistributed to a different well or wells, the increased pumping during Take Periods would not cause adverse water quality impacts related to drinking water standards, because the wells would still be operated by the SFPUC to meet such standards, as described in Chapter 3, Project Description, Section 3.4.2.2 (Well Facility Types). If decreased pumping were to occur, groundwater levels in the shallow water-bearing zone could increase slightly, with the potential for interaction with existing contamination. However, such an increase in the shallow water-bearing zone is unlikely and would be very small if it were to occur. Therefore, such potential impacts on groundwater quality would be *less than significant.*

If pumping were redistributed to a different well or wells, the increase in pumping would not cause significant water quality degradation related to constituents for which regulatory standards do not exist, because such constituents occur at very low levels that are not likely to be injurious to health (refer to Impact HY-14). Therefore, *no additional impacts* on groundwater quality would occur.

If pumping were redistributed, the total volume of Project pumping would remain the same, and therefore, *no impact* would occur on overall groundwater storage volumes in the Westside Groundwater Basin, and Project impacts related to groundwater depletion would therefore not change.

Hazards and Hazardous Materials

Implementation of M-HY-6 Actions #1, #2 and #9 would occur on existing golf club or cemetery property and would be similar in scope to ongoing irrigation activities at these facilities. Implementation of these actions would not involve the transport, use, or disposal of hazardous materials. Actions #3 and #4 would not involve construction activities and would also not involve the transport, use, or disposal of hazardous materials. As a result, *no such impacts* would occur for M-HY-6 Actions #1 through #4, and #9.

Implementation of M-HY-6 Actions #5, #6, #7, and #8 could require the use of hazardous materials during construction. Impacts related to accidental releases of chemicals (including within proximity to a school) could be *significant*. However, any activities involving the use or transport of hazardous materials would require compliance with applicable hazardous materials laws and regulations. Implementation of Mitigation Measure M-HY-1 (Develop and Implement a Stormwater Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan) would lessen the potential for impacts to *less than significant with mitigation* related to an accidental release of hazardous materials (including within proximity to a school) by requiring specific practices for the safe storage and handling of chemicals.

M-HY-6 Actions #7 and #8 would not include new structures. It is unknown whether implementation of M-HY-6 Actions #7 and #8 would result in the siting of a storage tank or a replacement irrigation well near a hazardous materials site identified on the Cortese List (described in Section 5.17, Hazards and Hazardous Materials). Siting the well near a hazardous materials site could result in the potential to encounter hazardous materials in soil or groundwater, which would be a *significant* hazardous materials impact. However, if these facilities were to be located near a hazardous materials site, implementation of Mitigation Measures M-HZ-2a (Preconstruction Hazardous Materials Assessment), M-HZ-2b (Health and Safety Plan), and M-HZ-2c (Hazardous Materials Management Plan) would reduce the potential hazardous materials impact on the environment to *less-than-significant* levels by requiring a soil investigation to determine the presence of chemical residue, as well as a soil and groundwater management plan to ensure appropriate handling and disposal of excavated material containing hazardous materials. No hazardous materials would be required during operation of M-HY-6 Actions #7 and #8. *No such potential impacts* during operation would therefore occur.

Mineral and Energy Resources

A portion of the Olympic Golf Club is mapped as MRZ-3, which indicates areas that contain mineral deposits, but the significance is unknown (CGS 1987, 1996). All other golf club and cemetery properties within the study area that may be subject to well interference are mapped as MRZ-1, which are areas with no significant mineral deposits or little likelihood for their presence, or MRZ-4, which are areas where information is inadequate for assignment to another zone (CGS 1987, 1996).

Implementation of M-HY-6 Actions #1 through #6, and #9 would not change existing land uses or otherwise change the availability of a known mineral resource. Therefore, no such impacts would occur. Implementation of M-HY-6 Actions #1, #2, #5, #6, and #9 could result in a small change in the energy use required by the irrigation systems or wells at the golf clubs and cemeteries. However, any such changes would be negligible in the context of the overall energy use at these facilities, and may actually reduce energy use. As a result, *no impacts* on minerals or energy resources would occur.

Construction of storage tanks (M-HY-6 Action #7) or replacement irrigation wells (M-HY-6 Action #8) would require the use of fossil fuels. However, given the nature and scale of construction, construction of M-HY-6 Actions #7 or #8 would not require a large amount of fuel or energy usage because of the moderate number of construction vehicles and equipment, worker trips, and truck trips that would be required for a project of this scale. Therefore, construction would not encourage activities that would result in the use of large amounts of fuel and energy. The impact would be *less than significant.* A storage tank or replacement irrigation well could be sited within the Olympic Golf Club area mapped as MRZ-3. However, implementation of these mitigation actions would not result in the loss of a known or locally important mineral resource because the site is not currently mined, and the placement of an aboveground storage tank or small irrigation well would not preclude future access to this resource or result in a change in this site's resource designation. Impacts on mineral and energy resources from M-HY-6 Actions #7 or #8 would therefore be *less than significant with mitigation*.

Agriculture and Forest Resources

A portion of the Holy Cross Cemetery property (areas east and west of Hillside Boulevard) is mapped by the Farmland Mapping and Monitoring Program as Unique Farmland, and a portion of the undeveloped property east of Hillside Boulevard is mapped as Grazing Land (CDC 2011). The area east of Hillside Boulevard also contains a small portion of forest land, as defined in PRC § 12220(g).

M-HY-6 Actions #1 through #6, and #9 do not involve changes to existing zoning, land use, or other construction that would result in the loss of important farmland or forest land. As a result, *no impacts* on agriculture or forest resources from these mitigation actions would occur.

M-HY-6 Actions #7 and #8 would be implemented on existing golf club and/or cemetery property. If a storage tank or replacement irrigation well were constructed in the Holy Cross cemetery area mapped as Unique Farmland, land actively used for agriculture would likely be avoided to the extent feasible, but a small portion of land mapped as Unique Farmland or Grazing Land could be displaced. However, the area of impact would be small and would not result in a conversion of land designated as Unique Farmland or Grazing Land to non-agricultural use, given that the overall land use would not change as a result of these mitigation actions. The land is not under a Williamson Act contract, and the implementation of M-HY-6 Actions #7 or #8 would not preclude continued and future use for agriculture, or involve other changes that could result in the conversion of agriculture land to some other use given that this is an irrigation supply action. Therefore, impacts on agriculture resources would be *less than significant*.

The Holy Cross Cemetery parcel also contains a small portion of forest land, as defined in PRC § 12220(g). However, sufficient non-forested land exists such that storage tanks could easily be sited to avoid the loss of forest land. *No impacts* on forest land would therefore occur.

Adverse Effects on Beneficial Uses of Lake Merced

This section provides an evaluation of whether there would be any significant impacts in addition to those identified for the Project due to implementation of Mitigation Measure M-HY-9b (Lake Level Management for Lake Merced). This mitigation measure lists a number of mitigation actions that may be undertaken by the SFPUC to meet the performance standard established in the mitigation measure. Two corrective actions are listed in the mitigation measure as examples of the types of actions that could result in a reduction of impacts at Lake Merced, as follows:

- Redistribute pumping to decrease Project pumping rates in the vicinity of Lake Merced or decrease the overall Project pumping rate. However, in no case would redistribution be undertaken where groundwater levels would decline more than from the Project as originally predicted by modeling.
- Augment lake levels through the addition of supplemental water (such as potable water that is dechloraminated at the Lake Merced Pump Station, stormwater from the Vista Grande Drainage Canal, recycled water, or stormwater diverted from other development in the Lake Merced watershed), if available.

Impacts related to implementation of this mitigation measure would not include any construction–related impacts, but could include hydrology and water quality impacts as follows:

Well Interference

Redistribution of pumping under Mitigation Measure M-HY-9b (Lake Level Management for Lake Merced) would not have the potential for additional well interference, because Mitigation Measure M-HY-9b specifies that redistribution of pumping would not occur in a manner that would cause groundwater levels to decline more from the Project than originally predicted by modeling. Therefore, impacts related to well interference would be l*ess than significant*.

Subsidence

Increased pumping at a Project well as a result of redistributed pumping could cause increased subsidence. However, the estimated maximum subsidence based on the proposed pumping distribution is less than 60 percent of the significance threshold (3.4 inches at Site 13 as shown in Table 5.16-15 (Estimated Subsidence due to Project Operations) compared to the significance threshold of six inches). Therefore, increased pumping, even at the well where the potential for subsidence is the greatest, would not likely result in subsidence in excess of the significance threshold for subsidence. As a result, impacts related to subsidence would be *less than significant*.

Seawater Intrusion

Increased pumping at a Project well as a result of redistributed pumping could result in an increased potential for seawater intrusion. However, Mitigation Measure M-HY-9b (Lake Level Management for Lake Merced) prohibits redistribution from being undertaken where groundwater levels would decline more than from the Project as originally predicted by modeling. Therefore, Mitigation Measure M-HY-9b would not increase the potential for seawater intrusion as compared to the Project, and Project impacts are less than significant. As a result, impacts related to adverse effects from Mitigation Measure M-HY-9b caused by seawater intrusion would be *less than significant*.

Adverse Effects on Beneficial Uses of Lake Merced

Addition of supplemental water to Lake Merced to maintain lake levels to avoid impacts on water quality, biological resources, and recreational resources could affect water quality, and therefore affect the beneficial uses of the lake. However, the discharge of supplemental water to the lake would be subject to oversight by the RWQCB, which would ensure that the water quality is sufficient to protect the beneficial uses of the lake. Therefore, there would be *less-than-significant* impacts on the beneficial uses of Lake Merced as a result of supplemental water additions.

Water Quality Standards

Increased pumping at a Project well as a result of redistributed pumping under Mitigation Measure M-HY-9b (Lake Level Management for Lake Merced) could increase the size of the groundwater protection zone at that well, potentially introducing new potentially contaminating activities. However, the Primary Production and Deep Aquifers would be protected from surface-level contamination within this large groundwater protection zone in the same manner that they are under the Project groundwater protection zones. Therefore, implementation of Mitigation Measure M-HY-9b would have *less-than-significant* impacts to water quality of the groundwater in the Westside Groundwater Basin.

Groundwater Depletion

Redistribution of pumping would not affect total groundwater storage, and, therefore, impacts related to groundwater depletion would be *less than significant*.

5.17 HAZARDS AND HAZARDOUS MATERIALS

This section describes hazardous materials and other hazards to public health and safety that could result from implementation of the proposed Project. It presents the potential construction and operational impacts of the Project related to hazards and hazardous materials, as well as mitigation measures as appropriate. This section also evaluates potential impacts from regional hazards including wildfire hazards, public use airports, and geologic units containing naturally occurring asbestos.

5.17.1 Setting

The study area for hazardous materials includes possible contaminating activities (e.g., known contaminant plumes, leaking underground storage tanks, dry cleaners, gas stations) within 0.25 mile of facility sites. The study area for the evaluation of airport and airstrip impacts is within two miles of each facility site and the study area for the evaluation of wildfires and emergency access is the facility site and the nearby areas surrounding the site. This section assesses the potential for hazardous materials to be present in the soil or groundwater as a result of a previously unidentified release of hazardous materials in the study area or a documented release of hazardous materials in or near the facility sites.

5.17.1.1 Definition of Hazardous Materials

The term "hazardous materials"[1] refers to both hazardous substances and hazardous wastes. Under federal and State laws, any material, including wastes, may be considered hazardous if it is specifically listed by statute as such or if it is toxic (causes adverse human health effects), ignitable (has the ability to burn), corrosive (causes severe burns or damage to materials), or reactive (causes explosions or generates toxic gases). The term "hazardous material" is defined as any material that, because of quantity, concentration, or physical or chemical characteristics, poses a significant present or potential hazard to human health and safety or to the environment if released into the workplace or the environment.

In some cases, past industrial or commercial activities on a site could have resulted in spills or leaks of hazardous materials to the ground, resulting in soil and/or groundwater contamination. Hazardous materials may also be present in building materials and released during building demolition activities. Hazardous materials may also be required as part of the operation of a project, or may be naturally present in soils such as naturally occurring asbestos (NOA) found in serpentine minerals.

---

[1] The California Health and Safety Code defines a hazardous material as "any material that, because of its quantity, concentration, or physical or chemical characteristics, poses a significant present or potential hazard to human health and safety, or to the environment. Hazardous materials include, but are not limited to, hazardous substances, hazardous waste, radioactive materials and any material which a handler or the administering agency has a reasonable basis for believing that it would be injurious to the health and safety of persons or harmful to the environment if released into the workplace or the environment" (Health and Safety Code, Section 25501).

If improperly handled, hazardous materials and wastes can cause public health hazards when released to the soil, groundwater, or air. The four basic exposure pathways through which an individual can be exposed to a chemical agent include: inhalation, ingestion, bodily contact, and injection. Exposure can come as a result of an accidental release during transportation, storage, or handling of hazardous materials. Disturbance of subsurface soil during construction can also lead to exposure of workers or the public from stockpiling, handling, or transportation of soils contaminated by hazardous materials from previous spills or leaks.

5.17.1.2 Potential Presence of Hazardous Materials in Soil and Groundwater

This evaluation of the potential to encounter hazardous materials in soil and groundwater is based on federal, State, and local regulatory database reviews conducted by Environmental Data Resources to identify permitted hazardous materials uses[2], environmental cases[3], and spill sites[4] within 0.25 mile of the facility sites (EDR 2008a-l). Additional information regarding identified cases was obtained from Preliminary Drinking Water Source Assessment and Protection[5] reports for facility sites, site investigation reports available from the State Water Resources Control Board (SWRCB) Geotracker database, as well as from the California Environmental Protection Agency (Cal/EPA) Department of Toxic Substances Control (DTSC) Envirostor online database (Kennedy/Jenks 2009a-g, 2010a-i; SWRCB 2012a; DTSC 2012). A list of the specific reports reviewed is provided in Section 5.17.4 (References).

Permitted hazardous material uses, environmental cases and spill sites identified within 0.25 mile of facility sites, including the well facility and associated pipelines, were characterized as to their potential to affect soil and groundwater that would be encountered during excavation for construction (i.e., subsurface conditions) at the facility sites according to the following classifications:

> **Low Potential.** Facilities that are permitted to use or store hazardous waste, but have not had a documented release, would be considered to have a low potential to affect facility sites. In addition, environmental cases that are listed as closed, because remediation or cleanup has been completed and approved by the regulatory agency, would be considered to have a low potential to affect proposed facility sites. The potential to affect subsurface conditions at a site would also be considered to be low if any of the following three factors is known to occur: (1) the direction of groundwater flow is away from the facility site construction area; (2) the lateral extent of contamination from the occurrence is known and is not present within the proposed facility site

---

[2] Permitted hazardous materials uses are facilities that use hazardous materials or handle hazardous wastes and comply with current hazardous materials and hazardous waste regulations.

[3] Environmental cases are sites suspected of releasing hazardous substances or sites that have required hazardous materials investigations and are identified on regulatory agency lists. These are sites where soil and/or groundwater contamination is known or suspected to have occurred.

[4] Spill sites are locations where a spill has been reported to the State or federal regulatory agencies. Such spills do not always involve a release of hazardous materials.

[5] The potential for groundwater contamination to affect drinking water quality and the potential for pumping of project wells to affect the extent of groundwater contamination is evaluated in Section 5.16, Hydrology and Water Quality.

construction area; or (3) only soil was affected by the occurrence and the potentially contaminated site is not located within the proposed facility site or immediately adjacent to the site (i.e., within 200 feet of the construction area).

Moderate Potential. The potential to affect subsurface conditions within a facility site would be considered to be moderate, and further investigation might be necessary, if the following three factors occur: (1) an off-site occurrence was reported within 0.25 mile of the facility site, but does not occur within the construction area; (2) the extent of contamination and remedial status is not known; and (3) the occurrence has affected groundwater and is located up-gradient from the facility site.

High Potential. The potential to affect subsurface conditions within the facility site would be considered to be high and further investigation would be necessary, if either of the following two factors is known to occur: (1) an active on-site occurrence exists within the proposed facility site construction area; or (2) contamination from an off-site occurrence is known to be present within the proposed facility site construction area.

Environmental cases and spill sites within 0.25 mile of proposed facility sites and their potential to affect soil and groundwater conditions in the project area during excavation are summarized in Table 5.17-1 (Hazardous Materials Release Sites Identified within 0.25 Mile of a Facility Site Construction Area). Environmental cases where the reporting agency has determined no further action is necessary (case closed) are not included in the table unless located within the well facility or immediately adjacent (i.e., within 200 feet) of a facility site and associated pipelines. In addition, facilities that are permitted to use or store hazardous waste, but have not had a documented release are not included in the table.

5.17.1.3 Potential Presence of Hazardous Building Materials

Demolition or renovation of older structures that contain hazardous building materials could present a public health risk if such materials were released during construction. Hazardous building materials include asbestos-containing materials[6] in roofing, siding, walls, ceilings, floors, pipes and pipe fittings; certain electrical equipment, such as transformers and fluorescent light ballasts that contain polychlorinated biphenyls (PCBs)[7] or di(2-ethylhexyl) phthalate (DEHP)[8]; fluorescent lights containing

---

[6] Asbestos-containing materials were commonly used until the 1970s as a component of numerous building materials. Long-term, chronic inhalation of asbestos can cause lung diseases. Asbestos may be present in numerous building materials, such as materials used to affix floor tiles, insulation materials, shingles, roofing materials, floor tiles and acoustical ceiling materials.

[7] PCBs are known carcinogens. They are mixtures of synthetic organic chemicals with physical properties ranging from oily liquids to waxy solids. Under the Toxic Substances Control Act, the US Environmental Protection Agency (U.S. EPA) began to impose bans on PCB manufacturing and sales on most PCB uses in 1978.

[8] Between 1979 and the early 1990s, DEHP was used in place of PCB as a dielectric fluid in some fluorescent light ballasts and other electrical equipment. DEHP is classified as a probable human carcinogen by the U.S Department of Health and Human Services and as a hazardous substance by the U.S. EPA. Ballasts containing DEHP must be legally disposed of.

mercury vapors[9]; and lead-based paints. If removed during demolition of a building, these materials would require special disposal procedures.

An existing concrete-block restroom building located within the construction area at Site 1 would be demolished as part of the Project. It is conservatively assumed for purposes of this analysis, that the restroom may contain hazardous building materials that could present a public health risk during demolition, such as asbestos and lead-based paint. The concrete block building includes sinks and toilets, plumbing, and electrical lighting materials. Internal and external building materials may contain asbestos in the flooring, roofing, pipes, and pipe fittings and the building may contain lead-based paint.

An existing well, concrete pump enclosure, steel tank, and above ground piping at Site 14 within the Golden Gate National Cemetery would be demolished as part of the Project. It is conservatively assumed for purposes of this analysis, that asbestos-containing materials may be present in the roofing, flooring, ceiling, and piping. The interior and exterior paint may also contain lead.

Building demolitions or renovations would not be needed at the other facility sites; therefore, hazardous building materials at sites other than Sites 1 and 14 would not be encountered.

5.17.1.4 Potential Presence of Naturally Occurring Asbestos

Asbestos is a common name for a group of naturally occurring fibrous silicate minerals that are made up of thin, but strong, durable fibers. Asbestos is a known carcinogen and presents a public health hazard if it is present in the friable (easily crumbled) form. Naturally occurring asbestos would most likely be encountered in Franciscan ultramafic rock (primarily serpentinite) or Franciscan mélange.

As discussed in Section 5.15, Geology and Soils, the underlying geology of the facility sites consists primarily of the Colma formation, with small pockets of alluvium deposits, slope debris/ravine fill and artificial fill. Franciscan ultramafic rock, including serpentinite, is not mapped in the vicinity of the proposed facility sites. In addition, Open File Report 2000-19, entitled *A General Location Guide for Ultramafic Rocks in California - Areas More Likely to Contain Naturally Occurring Asbestos*, was reviewed (CDC 2000). This report shows the areas more likely to contain natural occurrences of asbestos in California. According to this map, no ultramafic rock units occur in the areas of the proposed facility sites; therefore, naturally occurring asbestos is not likely to be encountered.

[9] Spent fluorescent lamps and tubes commonly contain mercury vapors and are considered a hazardous waste in California (California Code of Regulations [CCR], Title 22, Section 66261.50). In 2004, new regulations classified all fluorescent lamps and tubes in California as a hazardous waste, because they contain mercury. All fluorescent lamps and tubes must be recycled or taken to a universal waste handler.

TABLE 5.17-1
Hazardous Materials Release Sites Identified within 0.25 Mile of a Facility Site Construction Area

Site	Environmental Case within 0.25 Mile	Approximate Distance from Facility Site Construction Area	Regulatory List[(a)]	Environmental Case Summary	Potential to Affect Facility Site
Site 1	Tosco #3816 101 South Mayfair Avenue Daly City	1,000 feet northwest of Site 1	LUST	As of March 2012, the Tosco facility, located on the southwest corner of South Mayfair Avenue and Poncetta Drive, is undergoing soil investigation and remediation related to a former waste oil tank. Cleanup actions have included over excavation[(b)] and disposal of contaminated soil during tank removal as well as soil vapor extraction[(c)] for hydrocarbon removal (SWRCB 2012b). Sampling indicates that soil contamination is limited to the area surrounding the former and current tanks (no off-site migration). Only soil is affected, which, unlike contaminated groundwater, does not spread unless disturbed.	Low
Site 1	Pacific Plaza III 2099-2147 Junipero Serra Boulevard Daly City	1,200 feet southeast of Site 1	LUST	Pacific Plaza III is located on two parcels, one south of the intersection of Junipero Serra Boulevard and Westlake Avenue and another on the north side of the intersection. As of March 2012, the facility is undergoing soil investigation and remediation for arsenic, mercury and cadmium at isolated spots (SWRCB 2012c). Sampling indicates that soil contamination is limited to the area surrounding the release (minimal off-site migration) (Envirometrix 2009). Only soil is affected, which, unlike contaminated groundwater, does not spread unless disturbed.	Low
Site 2, Site 3 and Westlake Pump Station	Arco #0465 151 Southgate Avenue Daly City	1,200 feet northwest of Sites 2 and 3; 500 feet northeast of Westlake Pump Station	LUST	This facility, located at the southwest corner of Lake Merced Boulevard and Southgate Avenue, is an active gas station undergoing soil investigation and remediation as of March 2012. Cleanup actions have included overexcavation and disposal of contaminated soil during tank removal and soil vapor extraction for hydrocarbon removal (SWRCB 2012d). The documented groundwater flow direction at the Arco site varies from the northeast to south-southwest generally away from Sites 2 and 3 and the Westlake Pump Station (Stantec 2012). Sampling indicates that contamination is limited to the area surrounding the release (no off-site migration).	Low

TABLE 5.17-1
Hazardous Materials Release Sites Identified within 0.25 Mile of a Facility Site Construction Area

Site	Environmental Case within 0.25 Mile	Approximate Distance from Facility Site Construction Area	Regulatory List[(a)]	Environmental Case Summary	Potential to Affect Facility Site
Site 2, Site 3 and Westlake Pump Station	Southgate Cleaners 183 Southgate Avenue Daly City	1,200 feet northwest of Sites 2 and 3; 500 feet northeast of Westlake Pump Station	LUST	Southgate Cleaners, located at the southwest corner of Lake Merced Boulevard and Southgate Avenue near the Arco Station described above, is a former dry cleaning site undergoing soil and groundwater investigation for tetrachloroethylene (also known as perchloroethylene or PCE). As of March 2012, ongoing investigation work includes sub-slab soil and groundwater sampling on-site and in the vicinity of North Coronado Boulevard (SWRCB 2012e). The documented groundwater flow direction at the Arco #0465 site, which is adjacent to the Southgate Cleaners site, is toward the northeast to east, away from Sites 2 and 3 and the Westlake Pump Station (Treadwell & Rollo 2010). Sampling indicates that soil contamination is limited to the area surrounding the release (no off-site migration).	Low
Site 5	BP #11202 (Former) 3001 Junipero Serra Boulevard Daly City	450 feet north of Site 5	LUST	As of March 2012, this BP facility, located at the northeast corner of Junipero Serra Boulevard and San Pedro Road, is an active gas station undergoing soil investigation and remediation. Cleanup actions have included overexcavation and disposal of contaminated soil during tank removal as well as pumping and treatment of groundwater from an on-site monitoring well (SWRCB 2012f). The documented groundwater flow direction is to the north-northeast, away from Site 5 (Antea Group 2011). Sampling indicates that the groundwater plume is stable and limited to the area surrounding the release (no off-site migration).	Low
Site 5	Exxon 7-0207 1690 Sullivan Avenue Daly City	850 feet northwest of Site 5	LUST	Exxon 7-0207, located at the northwest corner of Sullivan Avenue and Pierce Street on the west side of I-280, is an active gas station undergoing soil investigation and remediation as of March 2012. Cleanup actions to date have included overexcavation and disposal of contaminated soil during tank removal and soil vapor extraction for hydrocarbon removal (SWRCB 2012g). The documented groundwater flow direction across the site is east to east-northeast , away from Site 5 (Cardno ERI 2011; SWRCB 2012g). Sampling indicates that soil and groundwater contamination is limited to the area surrounding the release (no off-site migration).	Low

TABLE 5.17-1
Hazardous Materials Release Sites Identified within 0.25 Mile of a Facility Site Construction Area

Site	Environmental Case within 0.25 Mile	Approximate Distance from Facility Site Construction Area	Regulatory List[(a)]	Environmental Case Summary	Potential to Affect Facility Site
Site 6	L. Bocci and Sons 7778 Mission Street Colma	800 feet east of Site 6	LUST	This facility, located near the Colma BART station at the intersection of Mission Street and Albert M. Tegla Boulevard, is a manufacturer of cemetery memorial monuments and is undergoing soil and groundwater investigation as of March 2012. Cleanup actions to date have included overexcavation and disposal of contaminated soil during tank removal (SWRCB 2012h). The documented groundwater flow direction is to the west-northwest and northwest, toward the Site 6 water connection pipeline. Sampling indicates that soil and groundwater contamination is limited to the area surrounding the release (minimal off-site migration) (TEC Environmental 2010a).	Low
Site 9	Treasure Island Trailer Court 1609 Old Mission Road South San Francisco	At least 50 feet northwest of Site 9; actual location of contaminant release within the trailer court is unknown	LUST	The trailer court, located on the west side of Mission Road, is a former LUST case site that has been closed since 1993, indicating that cleanup has been completed and residual contamination, if any, is low. Cleanup actions included overexcavation and disposal of contaminated soil during tank removal in 1991 (SWRCB 2012i). Database information regarding the environmental case indicates that only soil was affected, which, unlike contaminated groundwater, does not spread unless disturbed.	Low
Site 10 and Site 18 (Alternate)	WESCO Management 117 Hickey Boulevard South San Francisco	150 feet east of Site 10 and 1,200 feet northeast of 18 (Alternate)	LUST	The WESCO facility, located near Hickey Boulevard and Camaritas Avenue, is a former LUST case site that has been closed since 2000, indicating that cleanup has been completed and residual contamination, if any, is low. Cleanup actions included overexcavation and disposal of contaminated soil during tank removal in 1989 (SWRCB 2012j). Database information regarding the environmental case indicates that only soil was affected, which, unlike contaminated groundwater, does not spread unless disturbed.	Low
Site 11	Contreras Painting 1090 Grand Avenue South San Francisco	1,000 feet north of Site 11	Cortese	Contreras Painting, located near Grand Avenue and Mission Road, is a former residence that underwent soil and groundwater investigation for alleged unauthorized discharges of paint and solvent onto the exposed ground surface (SWRCB 2012k). Cleanup actions included excavating a trench alongside a house and in other hot spot areas on the property. The case site has been closed since June 2011, indicating that cleanup has been completed and residual contamination, if any, is low.	Low

TABLE 5.17-1
Hazardous Materials Release Sites Identified within 0.25 Mile of a Facility Site Construction Area

Site	Environmental Case within 0.25 Mile	Approximate Distance from Facility Site Construction Area	Regulatory List[(a)]	Environmental Case Summary	Potential to Affect Facility Site
Site 12 and Site 19 (Alternate)	Chevron, Former Standard Oil 972 El Camino Real South San Francisco	600 feet northeast of Site 12 and Site 19 (Alternate)	LUST	This facility, located on the east side of El Camino Real south of Westborough Boulevard, is a former gas station that underwent soil and groundwater investigation. No cleanup actions have been completed at the facility to date (SWRCB 2012l). The documented groundwater flow direction was to the east, away from Sites 12 and 19 (Alternate). Sampling indicates that soil and groundwater contamination was limited to the area surrounding the release (no off-site migration). The case site has been closed since March 2012, indicating that cleanup has been completed and residual contamination, if any, is low (San Mateo County Health System 2012).	Low
Site 12	Chevron 9-5669 698 El Camino Real South San Francisco	250 feet southeast of water connection pipeline for Site 12	LUST	This facility, located at the southeast corner of El Camino Real and West Orange Avenue, is a former LUST case site that was closed in 2007, indicating that cleanup has been completed and residual contamination, if any, is low. Cleanup actions have included overexcavation and disposal of contaminated soil during tank removal in 1994 (SWRCB 2012m).	Low
Site 12	Chevron 9-0248 687 El Camino Real South San Francisco	150 feet south of water connection pipeline for Site 12	LUST	This facility, located at the southwest corner of El Camino Real and West Orange Avenue, is a former LUST case site that was closed in 2001, indicating that cleanup has been completed and residual contamination, if any, is low. Information on cleanup actions was not documented in available database information (SWRCB 2012n).	Low
Site 13	Pacific Bell 1465 Huntington Avenue South San Francisco	<50 feet east of water connection pipeline along Huntington Avenue for Site 13	LUST	Pacific Bell, located on the east side of Huntington Avenue, is a former LUST case site that has been closed since 2010, indicating that cleanup has been completed and residual contamination, if any, is low. Cleanup actions included overexcavation and disposal of contaminated soil during tank removal in 1985, as well as soil vapor and dual phase extraction[(d)] for removal of hydrocarbons from soil and groundwater (SWRCB 2012o). The documented groundwater flow at the Pacific Bell site is toward the northeast, away from the water connection pipeline along Huntington Avenue for Site 13, as well as away from Site 13 itself (San Mateo County Health System 2010). The westernmost monitoring well at the Pacific Bell site nearest Huntington Avenue was historically non-detect for hydrocarbons. According to the case closure letter for the facility, the shallowest groundwater depth recorded at the site was approximately 21 feet below ground surface (bgs), which is below the depth of the proposed well facility pipeline trench (San Mateo County Health System 2010).	Low

TABLE 5.17-1
Hazardous Materials Release Sites Identified within 0.25 Mile of a Facility Site Construction Area

Site	Environmental Case within 0.25 Mile	Approximate Distance from Facility Site Construction Area	Regulatory List[(a)]	Environmental Case Summary	Potential to Affect Facility Site
Site 13	UNOCAL #6980 192 El Camino Real South San Francisco	1,000 feet west of water connection pipeline along Huntington Avenue for Site 13	LUST	The UNOCAL site, located at the northeast corner of El Camino Real and South Spruce Boulevard, is a former gas station undergoing soil and groundwater investigation and remediation as of March 2012. Cleanup actions to date have included overexcavation and disposal of contaminated soil during tank removal in 1992 (SWRCB 2012p). The documented groundwater flow direction in 2010 ranged from south to southwest, away from Site 13 (Arcadis 2010). Sampling indicates that soil and groundwater contamination is limited to the area surrounding the release (no off-site migration).	Low
Site 13	Tony's Services 209 El Camino Real South San Francisco	1,200 feet west of water connection pipeline along Huntington Avenue for Site 13	LUST	This facility, located at the northwest corner of El Camino Real and Hazelwood Drive, is a gas station undergoing soil and groundwater investigation and remediation as of March 2012. Cleanup actions to date have included overexcavation and disposal of contaminated soil during tank removal, soil vapor extraction, and pumping and treatment of groundwater (SWRCB 2012q). The documented groundwater flow direction is toward the west, away from Site 13 (AEI Consultants 2011).	Low
Site 13	Spruce Car Wash 246 South Spruce Avenue South San Francisco	650 feet northeast of Site 13	LUST	Spruce Car Wash, located on the north side of South Spruce Avenue near Myrtle Avenue, is an operating fuel service station and car wash undergoing soil and groundwater investigation and remediation as of March 2012 (SWRCB 2012r). Cleanup actions to date have included free product removal and pilot testing of vacuum enhanced groundwater extraction (GES 2011). Sampling indicates that soil and groundwater contamination is limited to the area surrounding the release with some off-site migration beneath Sneath Lane. The documented groundwater flow direction is toward the southeast away from Site 13 (GES 2010).	Low
Site 13	Coyne Cylinder Company 224 Ryan Way South San Francisco	1,000 feet east of Site 13	LUST	This facility, located on the north side of Ryan Lane near Victory Avenue, is undergoing soil and groundwater investigation related to a former acetone storage tank as of March 2012 (SWRCB 2012s). Cleanup actions to date have included overexcavation and disposal of contaminated soil during tank removal, as well as pumping and treating groundwater from an on-site well (Treadwell & Rollo 2008). Sampling indicates that soil and groundwater contamination is limited to the area surrounding the release (no off-site migration). The documented groundwater flow direction is toward the south, away from Site 13 (Treadwell & Rollo 2008).	Low

TABLE 5.17-1
Hazardous Materials Release Sites Identified within 0.25 Mile of a Facility Site Construction Area

Site	Environmental Case within 0.25 Mile	Approximate Distance from Facility Site Construction Area	Regulatory List[(a)]	Environmental Case Summary	Potential to Affect Facility Site
Site 13	Former Goss-Jewett Facility 416 Browning Way South San Francisco	650 feet east of water connection pipeline along Huntington Avenue for Site 13; 1,000 feet southeast of Site 13 well facility	CERCLA	This facility, located on the north side of Browning Way, is undergoing soil and groundwater investigation related to PCE contamination from a former dry cleaning business as of March 2012 (SWRCB 2012t). Based on monitoring data collected in October 2012, the groundwater flow direction appears to be to the north-northeast, which is away from Site 13 (KCE Matrix 2012). Recent sampling indicates that soil and groundwater contamination is limited to the area surrounding the release (minimal off-site migration) and appears to be essentially defined (KCE Matrix 2012). The PCE plume is heading to the north and northeast, away from Huntington Avenue and Site 13, in part due to the higher elevation of the existing trail to the west of the facility that prevents off-site flow to the west (RWQCB 2012).	Low
Site 13	290 South Maple Avenue South San Francisco	850 feet east of water connection pipeline along Huntington Avenue for Site 13; 1,200 feet southeast of Site 13 well facility	LUST CERCLIS	This facility, located on the northwest corner of South Maple Avenue and Browning Way, is undergoing soil and groundwater investigation related to PCE contamination from a former dry cleaning business as of March 2012. Cleanup actions to date have included excavation and disposal of contaminated soil (SWRCB 2012u). The documented groundwater flow direction at the site in September 2012 was toward the northeast, away from Huntington Avenue and Site 13 (GEI 2012).	Low
Site 13	Pellegrini Bros Wines Inc. 272 South Maple Avenue South San Francisco	1,000 feet east of water connection pipeline along Huntington Avenue for Site 13	LUST	This facility, located on the west side of South Maple Avenue, is undergoing soil and groundwater investigation and remediation related to hydrocarbons released from a former gasoline tank as of March 2012 (SWRCB 2012v). Cleanup actions to date have included overexcavation and disposal of contaminated soil during tank removal, as well as installation of an ozone and hydrogen peroxide injection remediation system (TEC Environmental 2011). The documented groundwater flow direction is toward the northeast, away from Site 13. Sampling indicates that soil and groundwater contamination is limited to the area surrounding the release (no off-site migration) (TEC Environmental 2011).	Low
Site 15	Golden Gate National Cemetery 1300 Sneath Lane San Bruno	100 feet north of pipeline connection for Site 15	LUST	This facility, located on the north side of Sneath Lane at the Cemetery Operation and Maintenance Facility, is a former LUST case site that was closed in 2005, indicating that cleanup has been completed and residual contamination, if any, is low. Cleanup actions included overexcavation and disposal of contaminated soil during tank removal in 1989 (San Mateo County Health Department 2005). Database information regarding the environmental case indicates that only soil was affected, which, unlike contaminated groundwater, does not spread unless disturbed (SWRCB 2012w).	Low

TABLE 5.17-1
Hazardous Materials Release Sites Identified within 0.25 Mile of a Facility Site Construction Area

Site	Environmental Case within 0.25 Mile	Approximate Distance from Facility Site Construction Area	Regulatory List[(a)]	Environmental Case Summary	Potential to Affect Facility Site
Site 16	Olympian Service Station 1009 El Camino Real Millbrae	200 feet west of the western end of the alternate water connection pipeline for Site 16	LUST	The Olympian Service Station, located on the northwest corner of El Camino Real and Meadow Glen Avenue, is undergoing soil and groundwater investigation and remediation related to former gasoline and diesel tanks. As of March 2012, cleanup actions to date have included overexcavation and disposal of contaminated soil during tank removal, and dual phase water and vapor extraction (SWRCB 2012x). A work plan for enhanced interim remediation using a bio-organic catalyst to enhance contaminant removal rates and accelerate contaminant bioattenuation is currently under review. The documented groundwater flow at the service station primarily is toward the southeast (on the service station property) to the east-northeast off-site, in the general direction of the proposed alternate water connection at Site 16 (Pangea 2011). Sampling indicates that the methyl tert-butyl ether (MTBE) plume in shallow groundwater extends across the intersection of El Camino Real to within approximately 200 feet of the western end of the alternate water connection pipeline for Site 16 (Pangea 2011). During the most recent site investigations, groundwater was encountered across El Camino Real to the west of the alternate water connection at depths ranging from 5.6 to 11.8 feet bgs. The site has moderate potential because the site is located within 0.25 miles of Site 16, the extent of contamination is not known, and the occurrence up gradient of Site 16.	Moderate
Site 16	San Francisco Water Department (SFWD) 1000 El Camino Real Millbrae	500 feet north of pipeline connections for Site 16	LUST	As of March 2012, the SFWD facility, located on the northeast corner of El Camino Real and Meadow Glen Lane, is undergoing soil and groundwater investigation and remediation related to an unintentional release of diesel from a backup generator in September 2010 (SWRCB 2012y). The majority of the spill was contained within the SFWD's corporation yard property, with approximately 10 to 15 gallons of diesel migrating onto the Caltrain right of way (GRI 2011). Cleanup actions to date have included removal and disposal of spilled diesel, storm drain cleaning and soil excavation in the Caltrain right of way. Sampling indicates that soil contamination is limited to a depth of eight feet in the area surrounding the release, approximately 500 feet from the well facility site.	Low
Site 16	Jiffy Cleaners 512 Magnolia Avenue Millbrae	1,200 feet south of alternate water connection pipeline for Site 16	LUST	As of March 2012, the Jiffy Cleaners facility, located at the northeast corner of Magnolia Avenue and Taylor Boulevard, is undergoing soil and groundwater investigation and remediation related to PCE contamination from a former dry cleaning facility (SWRCB 2012z). The documented groundwater flow direction at the cleaners is toward the east, away from Site 16. (TRC 2009).	Low

TABLE 5.17-1
Hazardous Materials Release Sites Identified within 0.25 Mile of a Facility Site Construction Area

Site	Environmental Case within 0.25 Mile	Approximate Distance from Facility Site Construction Area	Regulatory List[(a)]	Environmental Case Summary	Potential to Affect Facility Site
Site 16	Jerair Shell Station 491 El Camino Real Millbrae	1,200 feet south-southeast of alternate water connection pipeline for Site 16	LUST	As of March 2012, this facility, located on the southwest corner of EI Camino Real and Taylor Boulevard, is undergoing soil and groundwater investigation and remediation related to hydrocarbons released from former tanks. Cleanup actions to date have included overexcavation and disposal of contaminated soil during tank removal (SWRCB 2012aa). The documented groundwater flow is toward the east-southeast, away from Site 16 (TEC Environmental 2010b).	Low

Notes:

(a) Regulatory Lists: LUST (Leaking Underground Storage Tank List); Cortese (Cal/EPA List); CERCLIS (Comprehensive Environmental Response, Compensation, and Liability Information System). These lists are described in more detail in Section 5.17.2 (Regulatory Framework). Regulatory lists searched in April and May 2011, and again in March 2012.

(b) Overexcavation is a technique for the expedited corrective action of a limited release from an underground storage tank. Specifically, if a release is identified during the removal of a tank, the soil surrounding the tank pit area is often excavated to remove the contaminated materials.

(c) Soil vapor extraction is a remedial technology that reduces concentrations of volatile constituents in petroleum products adsorbed to soils in the unsaturated (vadose) zone.

(d) Dual phase extraction is a remedial technology that uses pumps to remove various combinations of contaminated groundwater, separate-phase petroleum product and hydrocarbon vapor from the subsurface.

5.17.1.5 Fire Hazards

The California Department of Forestry and Fire Protection (CAL FIRE) identifies fire hazard areas and fire-threatened communities at the wildland urban interface. The facility sites are located on urban land in non-fire hazard severity zones (CAL FIRE 2008).

The SFPUC maintains Lake Merced as a nonpotable emergency water supply for the City and County of San Francisco (CCSF) to be used for firefighting or sanitation purposes if no other sources of water are available (SFPUC 2011). In the event of a major disaster (i.e., catastrophic earthquake), Lake Merced water could be pumped into the City's drinking water distribution system to maintain firefighting, basic sanitary (e.g., toilet flushing), and other critical needs. In the event of such an emergency, residents would be directed to boil tap water before consuming it.

5.17.1.6 Airports

The nearest public airport to the facility sites is San Francisco International Airport (SFO), located approximately 1,600 feet northeast from Site 16 in Millbrae as measured from the proposed well facility to the SFO property boundary. In addition to Site 16, all proposed well facility sites in South San Francisco and San Bruno are within two miles of SFO and are located within an area covered by the San Mateo County Airport Land Use Plan. As a result, the well facility sites in Millbrae, South San Francisco and San Bruno would be subject to airport related height limitations and other airspace protection concerns for SFO. The other facility sites are not located within an area covered by an airport land use plan or within two miles of a public airport. No private airstrips occur in the project vicinity.

5.17.1.7 Hazardous Chemicals

Hazardous materials, such as fuels, motor oils, paints, and compressed gases, would be used during construction. While these are commonly used materials, if handled improperly, they could endanger workers and the public. In addition, a variety of commonly used chemicals would be used during operation of the chemical and filtration system for disinfection and water treatment; see Table 3-4 (Maximum Volume of Chemical Storage) in Chapter 3, Project Description, Section 3.4.2.2 (Well Facility Types).

5.17.2 Regulatory Framework

Hazardous materials and hazardous wastes are subject to numerous federal, State, and local laws and regulations intended to protect public health and safety and the environment. The U.S. Environmental Protection Agency (U.S. EPA), Cal/EPA, DTSC, Regional Water Quality Control Boards (RWQCB), and Bay Area Air Quality Management District (BAAQMD) are the primary agencies that enforce these regulations. The main focus of the federal Occupational Safety and Health Administration (Fed/OSHA) and California Occupational Safety and Health Administration (Cal/OSHA) are to prevent work-related injuries and illnesses, including those from exposures to hazardous materials. CAL FIRE implements fire safety regulations. In accordance with Chapter 6.11 of the California Health and Safety Code (CHSC, Section 25404, et seq.), local regulatory agencies enforce many federal and State regulatory programs through the Certified Unified Program Agency (CUPA) program, including:

- Hazardous Materials Business Plans (HMBPs) (Chapter 6.95 of the Health and Safety Code, Sections 25501 et seq.);
- State Uniform Fire Code requirements (Section 80.103 of the Uniform Fire Code as adopted by the State Fire Marshal pursuant to Health and Safety Code Section 13143.9);
- Underground storage tanks (Chapter 6.7 of the Health and Safety Code, Sections 25280 et seq.);
- Aboveground storage tanks (Health and Safety Code Section 25270.5[c]); and
- Hazardous waste generator requirements (Chapter 6.5 of the Health and Safety Code, Sections 25100 et seq.).

The San Mateo County Health Department, Environmental Health Division, is the CUPA agency for oversight of hazardous materials storage and cleanup of underground fuel leaks in San Mateo County.

5.17.2.1 Use and Storage of Hazardous Materials and Fuels

State and federal laws require detailed planning and management to ensure that hazardous materials are properly handled, used, stored, and disposed of, and, in the event that such materials are accidentally released, to reduce risks to human health and the environment. Businesses that handle specified quantities of chemicals are required to submit a HMBP in accordance with community right-to-know laws. This plan allows local agencies to plan appropriately for a chemical release, fire, or other incidents. Hazardous waste regulations establish criteria for identifying, packaging, and labeling hazardous wastes; dictate the management of hazardous waste; establish permit requirements for hazardous waste treatment, storage, disposal and transportation; and identify hazardous wastes that cannot be disposed of in landfills.

Chapter 6.95 of the CHSC (§ 25503 et seq.) and Title 19 of the California Code of Regulations (CCR) (§ 2729 et seq.), require any business that handles a hazardous material or mixture containing a hazardous material in reportable quantities to establish and implement a HMBP for emergency response to a release or threatened release of a hazardous material. The minimum reportable quantities are 500 pounds for a solid, 55 gallons for a liquid, and 200 cubic feet for a gas at standard temperature and pressure. Some acutely hazardous materials are reportable at much decreased quantities. Businesses in the Project area submit their plans to the appropriate CUPA. The HMBP must identify the type of business, location, emergency contacts, emergency procedures, mitigation plans, and chemical inventory at each location.

Certain chemicals that could be released to the environment and might affect surrounding communities are regulated by California's Accidental Release Prevention Law (CalARP). This State law and similar federal laws (i.e., the Emergency Preparedness and Community Right-to-Know Act [EPCRA], the Clean Air Act) allow local oversight of both the State and federal programs. The State and federal laws are similar in their requirements; however, the California threshold planning quantities for regulated substances are lower than the federal values. Local agencies may set lower reporting thresholds or add additional chemicals to the program. Beginning in 1997, CalARP has been implemented by the local CUPAs. Any business where the maximum quantity of a regulated substance exceeds the specified threshold quantities must register with the CUPA as a manager of regulated substances.

Ammonia is a regulated substance under State and federal risk management regulations. In accordance with CalARP regulations, preparation of a risk management plan (RMP) is required for the storage of regulated substances above threshold quantities. The listed CalARP threshold value for ammonia is 500 pounds (solid form). The ammonia component of the maximum volume of aqueous ammonia that would be stored at the proposed well facilities is below the CalARP threshold[10]. Therefore, storage of the ammonia at the facility sites would not be regulated under CalARP. Sod.ium hypochlorite, sodium hydroxide, and sodium fluoride are not regulated substances under CalARP.

The Construction General Permit which is issued under State Water Resources Control Board Order No. 2009-0009-DWQ, Waste Discharge Requirements for Discharges of Storm Water Runoff Associated with Construction and Land Disturbance Activities, applies to construction that in total disturbs one or more acres. This permit includes specific requirements for the safe storage and handling of chemicals. The best management practices (BMPs) required by the permit include protection measures for the temporary onsite storage of diesel fuels or other hazardous materials used during construction, including requirements for secondary containment and berming to contain a potential release and to prevent any such release from reaching an adjacent waterway or stormwater collection system. All equipment and materials storage would need to be routinely inspected for leaks and records maintained for documenting compliance with the storage and handling of hazardous materials. In addition, the Construction General Permit requires the development and implementation of a Storm Water Pollution Prevention Plan (SWPPP) for project-related construction activities at construction sites that disturb one or more acre of land.

Aboveground Storage of Petroleum Products

The Aboveground Petroleum Storage Act of 1990 requires facilities storing petroleum products in a single tank greater than 1,320 gallons, or facilities storing petroleum in aboveground tanks or containers with a cumulative storage capacity of greater than 1,320 gallons, to file a storage statement with the SWRCB and prepare a spill prevention, control, and countermeasure plan. The plan must identify appropriate spill containment or equipment for diverting spills from sensitive areas, as well as discuss facility-specific requirements for the storage system, inspections, recordkeeping, security, and personnel training. The SWRCB requires registration of an aboveground fuel storage tank at a construction site only if the tank is 20,000 gallons or larger, or if the aggregate volume of aboveground petroleum storage is over 100,000 gallons, which would not be applicable to the Project, since no fuel storage tanks are proposed as part of the Project. For smaller temporary tanks used during construction, methods to control releases and measures to clean up an accidental release and prevent degradation of water quality are included in

[10] Maximum of 116 gallons aqueous ammonia x 8.35 pounds per gallon (weight of water) x 0.93 (specific gravity of aqueous ammonia solution) x 0.19 (19% ammonia in solution) = 171 pounds of Ammonia.

Mitigation Measure HY-1 (Develop and Implement an Erosion and Sediment Control Plan) as described in Section 5.16, Hydrology and Water Quality.

Underground Storage Tanks

State laws governing underground storage tanks (USTs) specify requirements for permitting, monitoring, closure, and cleanup of these facilities. Regulations set forth construction and monitoring standards for existing tanks, reporting requirements for any releases, and closure requirements. In the Project area, the San Mateo County Environmental Health Division has regulatory authority for permitting, inspection, and removal of USTs. Any entity proposing to remove a UST must submit a closure plan to the County prior to tank removal. Upon approval of the UST closure plan, the County would issue a permit, oversee removal of the UST, require additional subsurface sampling if necessary, and issue a site closure letter when the appropriate removal and/or remediation has been completed. No USTs are proposed as part of the Project; however, these regulations are relevant due to the number of USTs in the vicinity of the Project with the potential to affect subsurface conditions at project sites.

5.17.2.2 Hazardous Materials Transportation

Caltrans regulates hazardous materials transportation on all interstate roads. Within California, the State agencies with primary responsibility for enforcing federal and State regulations and for responding to transportation emergencies are the California Highway Patrol (CHP) and Caltrans. Together, federal and State agencies determine driver-training requirements, load labeling procedures, and container specifications for vehicles transporting hazardous materials.

5.17.2.3 Hazardous Structural and Building Components

Numerous State and federal laws and regulations control exposure to hazardous building components, including asbestos and lead-based paint.

Lead in Construction

Cal/OSHA's Lead in Construction Standard (8 CCR 1532.1) requires project proponents to develop and implement a lead compliance plan when lead-based paint would be disturbed during construction. The plan must describe activities that could emit lead, methods for complying with the standard, safe work practices, and a plan to protect workers from exposure to lead during construction activities. Cal/OSHA requires 24-hour notification if more than 100 square feet of lead-based paint would be disturbed.

Abatement of Asbestos in Buildings and Structures

Regulatory requirements for asbestos abatement are set forth in CHSC Section 19827.5, as well as Title 8 of the CCR, Sections 341.6 through 341.14 and 1529. The BAAQMD also provides requirements for abatement of asbestos-containing materials.

CHSC Section 19827.5, adopted January 1, 1991, requires that local agencies not issue demolition or alteration permits until an applicant has demonstrated compliance with notification requirements under applicable federal regulations regarding hazardous air pollutants in the Bay Area, including asbestos. BAAQMD is vested by the California legislature with authority to regulate airborne pollutants, including asbestos. BAAQMD regulations pertaining to abatement of asbestos-containing materials are specified in Regulation 11, Hazardous Pollutants, Rule 2, Asbestos Demolition, Renovation, and Manufacture.

In accordance with this regulation, BAAQMD must be notified 10 days in advance of any proposed demolition or abatement work. This notification must include the names and addresses of operations and persons responsible; description and location of the structure to be demolished/altered, including size, age and prior use; approximate amount of friable asbestos; scheduled starting and completion dates of demolition or abatement; nature of planned work and methods to be employed; procedures to be employed to meet BAAQMD requirements; and the name and location of the waste disposal site to be used. In accordance with this regulation, a survey must be conducted to identify asbestos-containing materials prior to demolition. Containment must be provided during work that disturbs asbestos-containing materials and there must be no visible emissions to the outside air from demolition operations that involve asbestos-containing materials. The contractor must use methods specified in the regulations for control of emissions, such as wetting of exposed asbestos-containing materials; use of a high-efficiency particulate air (HEPA) filter within an exhaust, ventilation, and control system; or removal in an entirely contained chute. In addition, asbestos-containing materials must be removed prior to demolition and the work site must be cleaned of asbestos materials.

Contractors who conduct asbestos related work activities (including abatement) in buildings and structures must follow State regulations contained in 8 CCR Section 1529 and 8 CCR Sections 341.6 through 341.14 where the work would involve 100 square feet or more of asbestos-containing material. Specifically, under 8 CCR Section 341.6, Cal/OSHA must be notified of asbestos-related work activities to be performed. Contractors must be licensed as an Asbestos Qualified Contractor by the Contractors Licensing Board of the State of California, and registered as such with Cal/OSHA. In addition, a one-time report of the use of carcinogens must be made to Cal/OSHA under 8 CCR Chapter 4, Section 5203. The owner of the property where abatement is to occur must have a Hazardous Waste Generator Number assigned by and registered with the DTSC. The contractor and hauler of the material are required to file a Hazardous Waste Manifest that details the hauling of the material from the site and its disposal. Title 8 CCR Section 1529(b) defines asbestos-containing material as any material that contains more than one percent asbestos.

PCBs and Universal Wastes

Regulatory requirements for disposal of PCB wastes are set forth in 40 CFR Part 761. These requirements include identifying and labeling PCB-contaminated equipment prior to demolition, completion of a Notification of PCB Activity Form, obtaining a PCB disposal identification number, and disposing of waste at an approved PCB waste disposer under hazardous waste manifests. Regulatory requirements for disposal of universal wastes, such as mercury-containing non-incandescent lamps, batteries and other hazardous wastes commonly found in building components and equipment, are set forth in the Department of Toxic Substance Control's Universal Waste Rule (22 CCR Sections 66261.9 and 66273.1

thru 66273.90). These requirements include guidelines for removing and recycling or disposing of such wastes.

5.17.2.4 *Soil and Groundwater Contamination*

In San Mateo County, remediation of contaminated sites is generally performed under the oversight of the San Mateo County Environmental Health Division, or in some instances, the RWQCB and/or the DTSC. At sites where contamination is suspected or known to have occurred, the site owner is required to perform a site investigation and conduct site remediation, if necessary. Site remediation or development may also be subject to regulation by other agencies. For example, if a project required dewatering near a hazardous waste site, the project sponsor might be required to obtain a permit from the municipal sewer agency before discharging the water to the sewer system, or a National Pollutant Discharge Elimination System (NPDES) permit from the RWQCB before discharging to the storm water collection system.

5.17.2.5 *Worker Safety Requirements*

Fed/OSHA and Cal/OSHA are the agencies responsible for assuring worker safety in the handling and use of chemicals in the workplace. The federal regulations pertaining to worker safety are contained in Title 29 of the Code of Federal Regulations (CFR), as authorized in the Occupational Safety and Health Act of 1970. They provide standards for safe workplaces and work practices, including standards relating to hazardous materials handling. In California, Cal/OSHA assumes primary responsibility for developing and enforcing workplace safety regulations; Cal/OSHA standards are generally more stringent than federal regulations.

The State regulations concerning the use of hazardous materials in the workplace are included in Title 8 of the CCR, which contain requirements for safety training, availability of safety equipment, accident and illness prevention programs, hazardous substance exposure warnings, and emergency action and fire prevention plan preparation. Cal/OSHA also enforces hazard communication program regulations, which contain worker safety training and hazard information requirements, such as procedures for identifying and labeling hazardous substances, communicating hazard information related to hazardous substances and their handling, and preparation of health and safety plans to protect workers and employees.

At sites known or suspected to have soil or groundwater contamination, construction workers must receive training in hazardous materials operations and a site health and safety plan must be prepared. The health and safety plan establishes policies and procedures to protect workers and the public from exposure to potential hazards at the contaminated site.

5.17.2.6 *Control of Asbestos during Construction*

The California Air Resources Board (CARB) has adopted an asbestos Airborne Toxic Control Measure (ATCM) for construction and grading operations (CARB 2002). The ATCM requires the use of best available dust mitigation measures to prevent offsite migration of asbestos-containing dust from road construction and maintenance activities, construction and grading operations, and quarrying and surface mining operations in areas of ultramafic rock, serpentine, or asbestos. The regulation is implemented by the BAAQMD.

For construction projects located in areas where ultramafic rock (primarily serpentinite) is mapped and that would disturb one acre or less of land, the ATCM requires the site operator to implement standard dust mitigation measures before construction begins, and to maintain each measure throughout the duration of the construction project. For construction activities that would disturb more than one acre of asbestos-containing materials, project sponsors are required to prepare an asbestos dust mitigation plan specifying measures that would be taken to ensure that no visible dust crosses the property boundary. The asbestos dust mitigation plan must be submitted to and approved by the BAAQMD prior to the beginning of construction. The site operator must ensure the implementation of all measures throughout the construction project. In addition, the BAAQMD could require air monitoring for offsite migration of asbestos dust during construction activities and might change the plan on the basis of the air monitoring results. As discussed in Section 5.17.1.4 (Potential Presence of Naturally Occurring Asbestos) mapping does not indicate the presence of ultramafic rock units in the areas of the proposed facility sites; therefore, the Asbestos ATCM would not apply to the proposed Project.

5.17.2.7 Risk of Fires

The California Public Resources Code (PRC) sets forth fire safety regulations that include the following:

- Earthmoving and portable equipment with internal combustion engines must be equipped with a spark arrestor to reduce the potential for igniting a wildland fire (PRC Section 4442).
- Appropriate fire suppression equipment must be maintained during the highest fire danger period – from April 1 to December 1 (PRC Section 4428).
- On days when a burning permit is required, flammable materials must be removed to a distance of 10 feet from any equipment that could produce a spark, fire, or flame, and the construction contractor would maintain the appropriate fire suppression equipment (PRC Section 4427).
- On days when a burning permit is required, portable tools powered by gasoline-fueled internal combustion engines must not be used within 25 feet of any flammable materials (PRC Section 4431).

As noted in Section 5.17.1.5 (Fire Hazards), the proposed Project would be located on urban land in zones designated as "Non-Fire Hazard" by CAL FIRE (CAL FIRE 2008).

5.17.2.8 Uniform Fire Code

The Uniform Fire Code, Article 80, includes specific requirements for the safe storage and handling of hazardous materials. These requirements are intended to reduce the potential for a release of hazardous materials and for mixing of incompatible chemicals and specify the following specific design features to reduce the potential for a release of hazardous materials that could affect public health or the environment:

- Separation of incompatible materials with a noncombustible partition;
- Spill control in all storage, handling, and dispensing areas; and
- Separate secondary containment for each chemical storage system. The secondary containment must hold the entire contents of the tank, plus the volume of water needed to supply the fire suppression system for a period of 20 minutes in the event of catastrophic spill.

5.17.2.9 Emergency Response

California has developed an emergency response plan to coordinate emergency services provided by federal, State, and local government, and private agencies. Responding to hazardous materials incidents is a part of this plan. The plan is administered by the State Office of Emergency Services (OES), which coordinates the responses of other agencies. The San Mateo County Emergency Response Team (ERT) coordinates response to hazardous materials emergencies within the project area. ERT members respond and work with local fire and police agencies, emergency medical providers, CHP, the California Department of Fish and Wildlife, and Caltrans. San Mateo County, Daly City, Colma, South San Francisco, San Bruno, and Millbrae all have adopted emergency response plans. The emergency response plans do not designate specific evacuation routes within these cities (Colma Fire Department 2012; NCFA 2012; San Mateo County Sherriff's Office of Emergency Services 2012; RWQCB 2012; South San Francisco Fire Department 2012).

5.17.2.10 Airport Operations

The Federal Aviation Administration (FAA) has jurisdiction over airspace in the U.S. FAA requirements as they relate to land uses near SFO are described below.

The Federal Aviation Regulations (FAR) provide criteria for evaluating the potential effects of obstructions on the safe and efficient use of navigable airspace within approximately two to three miles of airport runways and approximately 9.5 miles from the end of high-traffic runways that have a precision instrument approach. FAA requires notification of proposed construction or alteration projects identified by the following airspace obstruction criteria provided in FAR Part 77:

- Any construction or alteration of more than 200 feet in height above the ground level at its site.
- Any construction or alteration of greater height than an imaginary surface extending outward 100 feet and upward one foot for a horizontal distance of 20,000 feet from the nearest point of the nearest runway of an airport with at least one runway more than 3,200 feet in actual length.
- Any construction or alteration of greater height than an imaginary surface extending outward 50 feet and upward one foot for a horizontal distance of 10,000 feet from the nearest point of the nearest runway of an airport with its longest runway no more than 3,200 feet in actual length.

Under the California State Aeronautics Act, local governments have the authority to protect airspace as defined by criteria provided in FAR Part 77. The City/County Association of Governments of San Mateo is the Airport Land Use Commission (ALUC) and has adopted the San Mateo County Comprehensive Airport Land Use Plan, which incorporates and in some cases exceeds the criteria provided in FAR Part 77 (C/CAG 1996). Other airspace protection concerns described in FAR Part 77 include avoiding land uses in the airport vicinity that would create hazards to flight such as electrical interference, lighting, glare, smoke, and bird strikes.

5.17.3 Impacts and Mitigation Measures

5.17.3.1 Significance Criteria

For the purposes of this EIR, the Regional Groundwater Storage and Recovery Project would have a significant impact on hazards and hazardous materials if it were to:

- Create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials.
- Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment.
- Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within 0.25 mile of an existing or proposed school.
- Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would create a significant hazard to the public or the environment.
- Be located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, and would result in a safety hazard for people residing or working in the project area.
- Be located within the vicinity of a private airstrip and would result in a safety hazard for people residing or working in the project area.
- Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan.
- Expose people or structures to a significant risk of loss, injury, or death involving fires.

5.17.3.2 Approach to Analysis

This impact analysis focuses on the potential to encounter hazardous substances in soil and groundwater during construction and the potential to discharge hazardous materials during Project operations.[11] The evaluation was performed in light of current conditions at the proposed facility sites, information in the environmental database, site investigation reports, applicable regulations and guidelines, and proposed construction activities and operations. The analysis also addresses the potential for the Project to encounter hazardous materials during building demolition activities; result in a release of hazardous materials from construction equipment; interfere with an adopted emergency response plan or emergency evacuation plan; create fire hazards; or result in a release of hazardous materials during operation. Each potential impact is assessed in terms of the applicable regulatory requirements, and mitigation measures are identified as appropriate.

Areas of No Project Impact

As explained below, the Project would not result in impacts related to three of the above-listed significance criteria. These significance criteria are not discussed further in the impact analysis for the following reasons:

Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would create a significant hazard to the public or the environment. According to the environmental database review, Project facilities are not included on any lists of hazardous materials sites compiled pursuant to Government Code Section 65962.5. Therefore, this criterion is not applicable to the proposed Project and is not discussed further.

Be located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, and would result in a safety hazard for people residing or working in the project area. This significance criterion is intended to address facility siting and design impacts and does not apply to temporary construction impacts. Therefore, this significance criterion is not applicable to Project construction activities and is only discussed below as it relates to long-term operational impacts.

Be located within the vicinity of a private airstrip and would result in a safety hazard for people residing or working in the project area. Proposed well facilities would not be located within the vicinity of a private airstrip. Therefore, this significance criterion is not applicable to construction or operation of the Project.

Impair implementation of, or physically interfere with, an adopted emergency response plan or emergency evacuation plan. San Mateo County, Daly City, Colma, South San Francisco, San Bruno, and

[11] Potential effects of exhaust emission from construction activities in the vicinity of schools and other sensitive receptors is described in Section 5.8, Air Quality, Impact AQ-3.

Millbrae all have adopted emergency response plans. The emergency response plans do not designate specific evacuation routes or sites within the cities (Colma Fire Department 2012; NCFA 2012; San Mateo County Sherriff's Office of Emergency Services 2012; RWQCB 2012; South San Francisco Fire Department 2012). Therefore, neither Project construction nor operation, including pipeline installations that would extend into adjacent roadways, would impair implementation of or physically interfere with any adopted emergency response or evacuation plan. Section 5.6, Transportation and Circulation, further discusses anticipated lane closures that would be required during construction.

5.17.3.3 Summary of Impacts

For the significance criteria that have not already been deemed "not applicable" in the Approach to Analysis section above, the specific impact analyses below are divided into two subsections: (1) construction impacts (short-term) and (2) operational impacts (long-term). Table 5.17-2 (Summary of Impacts – Hazards and Hazardous Materials) provides a summary of potential impacts from the proposed Project.

Notes:

NI = No Impact

LS = Less than Significant Impact

LSM = Less than Significant with Mitigation

5.17.3.4 Construction Impacts and Mitigation Measures

Impact HZ-1. The Project would not create a significant hazard to the public or the environment related to transport, use, or disposal of hazardous materials during construction. (Less than Significant)

<u>All Sites</u>

Project construction activities would include the use of hazardous materials such as fuels, lubricants, paints, and solvents. Numerous laws and regulations ensure the safe transportation, use, storage, and disposal of hazardous materials (see Section 5.17.2, Regulatory Framework). Routine transport of hazardous materials to and from proposed facility sites could result in an incremental increase in the potential for accidents; however, Caltrans and CHP regulate the transportation of hazardous materials and wastes, including container types and packaging requirements, as well as licensing and training for truck operators, chemical handlers, and hazardous waste haulers. Worker safety regulations cover hazards related to the prevention of exposure to hazardous materials and a release to the environment from hazardous materials use. Regulations and criteria for the disposal of hazardous materials mandate disposal at an appropriate landfill. Cal-OSHA also enforces hazard communication program regulations, which contain worker safety training and hazard information requirements, such as procedures for identifying and labeling hazardous substances, communicating hazard information related to hazardous substances and their handling, and preparation of health and safety plans to protect workers and employees.

Therefore, because the SFPUC and its contractors would be required to comply with existing and future hazardous materials laws and regulations covering the transport, use, and disposal of hazardous materials, the impacts associated with the potential to create a significant hazard to the public or the environment would be *less than significant*.

Impact Conclusion: Less than Significant

Impact HZ-2. The Project would result in a substantial adverse effect related to reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment during construction. (Less than Significant with Mitigation)

Accidental Release of Hazardous Chemicals during Construction

<u>All Sites</u>

There are two types of accidental releases that could occur during construction. Hazardous materials are routinely used during construction activities and there is a potential for an accidental release associated with this routine use during construction. In addition, construction involves excavation that could encounter contaminated soil or groundwater that are already present at the construction site. Each type of accidental release is discussed below.

Hazardous materials assumed by this analysis to be used during construction activities include fuels, lubricants, paints, and solvents. Storage and use of hazardous materials at construction sites and staging areas could potentially result in the accidental release of small quantities of hazardous materials, which could pose a risk to construction workers and the environment, such as degradation of soil and groundwater quality and/or surface water quality.

The greatest potential for encountering contaminated soil and groundwater during construction would be in areas where past or current land uses may have resulted in leaking fuel or chemical storage tanks or other releases of hazardous materials. Properties with known soil and/or groundwater contamination are referred to as "environmental cases." As identified in Section 5.17.1 (Setting) and Table 5.17-1 (Hazardous Materials Release Sites Identified within 0.25 Mile of a Facility Site Construction Area), 26 environmental cases included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 are located within 0.25 mile of proposed facility sites and have some potential to affect subsurface conditions at project locations.

No active environmental cases were identified within 0.25 mile of Sites 4, 7, 8, 9, 14, and 17 (Alternate). In addition, no closed environmental cases were located on site or immediately adjacent to these sites. Therefore, the potential to encounter hazardous materials in soil or groundwater at these sites would be low. Although the potential to encounter hazardous materials in soil or groundwater at these sites arising from off-site sources is low, site conditions could change prior to construction if new contaminated sites are identified in the vicinity of these proposed well facilities. If new contamination sites were located at or near these sites, the potential hazardous materials impact would be *significant.*

Several environmental cases included on a list of hazardous materials sites are located within 0.25 mile of Sites 1, 2, 3, 5, 6, 10, 11, 12, 13, 15, 18 (Alternate), 19 (Alternate), and the Westlake Pump Station. The potential to encounter hazardous materials in soil or groundwater at these proposed facility sites is low because hazardous material release sites have not resulted in soil or groundwater contamination in the immediate vicinity of the well facilities. Similar to the findings above, although the potential to encounter hazardous materials in soil or groundwater at these sites arising from off-site sources is low, site conditions could change prior to construction if new contaminated sites are identified in the vicinity of proposed well facilities or if there are substantial changes in the extent of contamination at known release sites. Therefore, the potential hazardous materials impact would be *significant*.

Four environmental cases are located within 0.25 mile of Site 16. The Jiffy Cleaners and Jerair Shell Station cases are at least 1,200 feet (0.23 mile) away from the nearest excavation area associated with Site 16 and have a low potential to affect subsurface excavations at Site 16 because the direction of groundwater flow is away from Site 16 (TRC 2009; TEC Environmental 2010b). Also, the San Francisco Water Department case is at least 500 feet (0.095 mile) away from Site 16 and has a low potential to affect potential subsurface excavations associated with Site 16 because remedial action is underway and sampling indicates that soil contamination is limited to the area surrounding the release (GRI 2011). Off-site contamination from the Olympian Service Station case is located within approximately 200 feet from the alternate water connection for Site 16 and has a moderate potential to affect subsurface excavations in the area. The potential for this impact is considered moderate because the documented occurrence of contamination is in close proximity to the alternate water connection pipeline route and the extent of contamination from the case has not been laterally delineated, the groundwater flow is in the general direction of the construction area, and the most recent data about off-site depth to groundwater in the vicinity of the alternate water connection pipeline indicates groundwater could be encountered during trenching (i.e., less than six feet bgs) (Pangea 2011). Therefore, given that the potential to encounter hazardous materials in soil or groundwater at Site 16 is moderate, and due to the proximity and nature of construction activities, construction of the Project at this location could cause a significant hazardous materials impact on the public or the environment by exposing people to contaminated soil or groundwater or soil vapors during excavation and other ground-disturbing pipeline construction activities. As a result, the potential hazardous materials impact on the environment from constructing the alternate water connection for Site 16 would be *significant*.

The potential impact associated with construction at all the above sites would be reduced to a *less-than-significant* level with implementation of Mitigation Measures M-HZ-2a (Preconstruction Hazardous Materials Assessment), M-HZ-2b (Health and Safety Plan), and M-HZ-2c (Hazardous Materials Management Plan). These measures require: (1) a preconstruction hazardous materials assessment within three months of construction to identify new hazardous materials sites or substantial changes in the extent of contamination at known groundwater contamination sites that could affect subsurface conditions at proposed well facility sites; (2) preparation of a site health and safety plan to protect construction worker health and safety; and (3) a hazardous materials management plan to ensure that appropriate procedures are followed in the event that hazardous materials, including unanticipated hazardous materials, are encountered during project construction, and to ensure that hazardous materials are transported and disposed of in a safe and lawful manner.

In addition, the implementation of Mitigation Measure M-HY-1 (Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan), which is required to reduce potential impacts on water quality during Project construction (see Impact HY-1 in Section 5.16, Hydrology and Water Quality), would also reduce this potential hazardous materials impact to a *less-than-significant* level. While this mitigation measure is presented in Section 5.16, Hydrology and Water Quality, and primarily addresses potential water quality impacts, it also contains measures for controlling non-stormwater (i.e., excavation dewatering), waste, and potential hazardous materials pollution, which would also reduce the potential for the accidental release of hazardous construction chemicals. The Erosion and Sediment Control Plan requires specific practices for the safe storage and handling of chemicals. The BMPs required to be in the plan include protection measures for the temporary on-site storage of diesel fuels or other hazardous materials used during construction, including requirements for secondary containment to contain a potential release and to prevent any such release from reaching an adjacent waterway or stormwater collection system. All equipment and materials storage would need to be routinely inspected for leaks and records maintained for documenting compliance with the storage and handling of hazardous materials. With the incorporation of these BMPs, the potential hazardous materials impact on the public or environment from an accidental release of hazardous materials during construction would be *less than significant with mitigation*.

Mitigation Measure M-HZ-2a: Preconstruction Hazardous Materials Assessment (All Sites)

Within three months prior to construction, the SFPUC shall retain a qualified environmental professional to conduct a regulatory agency database review to update and identify hazardous materials sites within 0.25 mile of a well facility site and to review appropriate standard information sources to determine the potential for soil or groundwater contamination at the project sites. Should this review indicate a high likelihood of encountering contamination at the proposed facility sites, follow-up sampling shall be conducted to characterize soil and groundwater quality prior to construction to provide necessary data for the site health and safety plan (Mitigation Measure M-HZ-2b) and hazardous materials management plan (Mitigation Measure M-HZ-2c). If needed, site investigations or remedial activities shall be performed at facility sites in accordance with applicable laws and regulations.

Mitigation Measure M-HZ-2b: Health and Safety Plan (All Sites)

The construction contractor shall, prior to construction, prepare a site-specific health and safety plan in accordance with federal OSHA regulations (29 CFR 1910.120) and Cal-OSHA regulations (8 CCR Title 8, Section 5192) to address worker health and safety issues during construction. The health and safety plan shall identify the potentially present chemicals, health and safety hazards associated with those chemicals, all required measures to protect construction workers and the general public from exposure to harmful levels of any chemicals identified at the site (including engineering controls, monitoring, and security measures to prevent unauthorized entry to the work area), appropriate personal protective equipment, and emergency response procedures. The health and safety plan shall designate qualified individuals responsible for implementing the plan and for directing subsequent procedures in the event that unanticipated contamination is encountered.

Mitigation Measure M-HZ-2c: Hazardous Materials Management Plan (All Sites)

The contractor shall, prior to construction, prepare a hazardous materials management plan that specifies the method for handling and disposal of both chemical products and hazardous materials during construction and contaminated soil and groundwater, should any be encountered during construction. Contract specifications shall mandate full compliance with all applicable local, State, and federal regulations related to identifying, transporting, and disposing of hazardous materials, including hazardous building materials (i.e., asbestos containing materials, lead-based paint, and electrical equipment) and any hazardous wastes encountered in excavated soil or groundwater. The contractor shall provide the SFPUC with copies of hazardous waste manifests documenting that disposal of all hazardous materials has been performed in accordance with the law.

If contaminated soil or groundwater is encountered, the SFPUC shall require the construction contractor to prepare and implement a construction Soil and Groundwater Management Plan. The contractor shall submit the Plan to the SFPUC and the San Mateo County Department of Health Services, Groundwater Protection Program, for review and approval. Elements of the plan shall include:

- Measures to address hazardous materials and other worker health and safety issues during construction, including the specific level of protection required for construction workers.

- Provisions for excavation of soil, stockpiling, dust, and odor control measures.

- Measures to prevent off-site migration of contaminated soil and groundwater.

- Location and final disposition of all soil and groundwater removed from the site.

- All other necessary procedures to ensure that excavated materials are stored, managed, and disposed of in a manner that is protective of human health and in accordance with applicable laws and regulations.

Mitigation Measure M-HY-1: Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan (All Sites)
(See Impact HY-1 in Section 5.16, Hydrology and Water Quality, for description.)

Impact Conclusion: Less than Significant with Mitigation

Hazardous Building Materials

The evaluation of impacts that follows discusses sites with no impacts first, followed by sites with less-than-significant impacts.

<u>Sites 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 15, 16, 17 (Alternate), 18 (Alternate), 19 (Alternate), and the Westlake Pump Station</u>

Construction at these facility sites would not result in exposure of construction workers or the public to hazardous building materials because building demolition would not occur at any of these sites. Therefore, there would be *no impact* at these sites relative to the potential to create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment from hazardous building materials.

Impact Conclusion: No Impact

<u>Sites 1 and 14</u>

At Site 1, an existing concrete restroom building would be demolished. At Site 14, an existing well, concrete pump enclosure, steel tank, and aboveground piping would be demolished. Lead-based paint may be present on the interior of the restroom building at Site 1, as well as on the exterior and interior of the concrete pump enclosure at Site 14. In addition, asbestos-containing materials could be present in the roofing, flooring, ceiling, and piping (i.e., transit pipe and fittings) at the sites. PCB-containing electrical equipment, fluorescent light ballast containing DEHP, and fluorescent light tubes containing mercury could also be present in electrical equipment at either Site 1 or Site 14.

Cal/OSHA's Lead in Construction Standard, described above in Section 5.17.2.3 (Hazardous Structural and Building Components), addresses the safe handling of lead-based paint during demolition. The SFPUC would sample the lead content in the paint at both demolition sites to determine whether the Standard applies. If lead were detected, the construction contractor would be required to comply with the standard. The standard requires that a contractor develop and implement a lead compliance plan, which must include a description of the activities that could emit lead, methods that will be used to meet the safe work practices, Cal/OSHA notification requirements, and a plan to protect workers from lead exposure during construction activities. Therefore, compliance with the regulations and procedures already established would ensure that potential impacts due to disturbance of lead-based paint during demolition would be *less than significant*.

There are well-established regulatory requirements for asbestos abatement in structures, described above in Section 5.17.2.3 (Hazardous Structural and Building Components). For example, in accordance with BAAQMD Regulation 11, Rule 2 (Asbestos Demolition, Renovation and Manufacture), a survey must be conducted to identify asbestos-containing materials prior to demolition, and the BAAQMD must be notified 10 days in advance of any proposed demolition or abatement work. Containment must be provided during work that disturbs asbestos-containing materials and there must be no visible emissions to the outside air from demolition operations that involve asbestos-containing materials. The contractor must use methods specified in the regulations for control of emissions, such as wetting of exposed asbestos-containing materials; use of a high-efficiency particulate air (HEPA) filter within an exhaust, ventilation and control system; or removal in an entirely contained chute. The contractor and hauler of the material are required to file a Hazardous Waste Manifest that details the hauling of the material from the site and its disposal. Therefore, compliance with the required handling and disposal procedures already established would ensure that potential impacts due to disturbance of asbestos during demolition would be *less than significant*.

The U.S. EPA's PCB regulations (40 CFR Part 761) regulates the disposal of PCB wastes generated or encountered during construction, including PCB-contaminated soils or equipment discovered during demolition. The SFPUC would be required to identify and label PCB-contaminating equipment prior to demolition. The EPA must be notified prior to disposal through completion of a Notification of PCB Activity Form, which would include establishing an ID number for activities involving PCBs. The regulations require that the waste be disposed of at an approved PCB waste disposer under a hazardous materials manifest. In addition, the Department of Toxic Substance Control's Universal Waste Rule (22 CCR Sections 66261.9 and 66273.1 thru 66273.90) provides guidelines for removal and recycling / disposal of universal wastes, such as mercury-containing non-incandescent lamps, batteries and other hazardous wastes commonly found in building components and equipment. Therefore, compliance with the regulations and procedures already established would ensure that potential impacts due disposal of PCB-containing equipment or other universal wastes during demolition would be *less than significant*.

Impact Conclusion: Less than Significant

Impact HZ-3. The Project would result in impacts from the emission or use of hazardous materials within 0.25 mile of a school during construction. (Less than Significant with Mitigation)

The evaluation of impacts that follows discusses sites with no impacts first, followed by sites with less-than-significant impacts, and sites with significant impacts.

During construction, potentially hazardous materials could be used or stored near a school. As shown in Table 5.17-3 (Schools within 0.25 Mile of a Proposed Facility Site Construction Area), 10 schools are located within approximately 0.25 mile of a proposed facility site. Potentially hazardous materials typically used for construction would include lubricants, degreasers, paints, solvents, and fuels. The impacts of construction-related truck and vehicle emissions in proximity to schools (and other sensitive receptors) are discussed in Section 5.8, Air Quality, Impact AQ-3.

TABLE 5.17-3
Schools within 0.25 Mile[(a)] of a Proposed Facility Site Construction Area

Schools	Sites within 0.25 Mile
Ben Franklin Intermediate School	• Site 2 is approximately 60 feet (0.01 mile) east of the school property, across Park Plaza Drive. • Site 3 is located within the school property. • Site 4 is approximately 100 feet (0.02 mile) southeast of the school property. • The Westlake Pump Station is immediately adjacent to a school playing field.
Garden Village Elementary School	• Site 2 is approximately 30 feet (0.006 mile) north of the school property. • Site 3 is approximately 330 feet (0.06 mile) west of the school property. • Site 4 is located immediately adjacent to the school playing field.
Margaret Brown Elementary School	• Site 5 is approximately 1,200 feet (0.23 mile) east of the school, across Interstate Highway 280 (I-280).
Hope Lutheran Elementary School	• Site 5 is approximately 1,200 feet (0.23 mile) northeast of the school, across I-280. • Site 6 is approximately 1,050 feet (0.20 mile).
Holy Angeles Elementary School	• Site 5 is approximately 475 feet (0.09 mile) southwest of the school, across the BART tracks.
El Camino High School	• Site 9 is approximately 1,100 feet (0.21 mile) northwest of the school.
Alta Loma Middle School	• Site 9 is approximately 1,275 feet (0.24 mile) northeast of the school, across El Camino Real. • Site 10 is approximately 950 feet (0.18 mile) northwest of the school. • Site 18 (Alternate) is approximately 170 feet (0.03 mile) northwest of the school.
R.W. Drake Preschool	• Site 12 is 100 feet (0.018 mile) south of the school. • Site 19 (Alternate) is immediately adjacent to the school.
Baden High School	• Site 12 is 920 feet (0.17 mile) northeast of the school. • Site 19 (Alternate) is 900 feet (0.17 mile) northeast of the school.
Los Cerritos Elementary School	• Site 12 is 930 feet (0.17 mile) northwest of the school, across El Camino Real. • Site 19 (Alternate) is 1,250 feet (0.23 mile) northwest of the school, across El Camino Real.
South San Francisco High School	• Site 12 is approximately 1,000 feet (0.19 mile) northwest of the school, across El Camino Real. • Site 13 is approximately 900 feet (0.17 mile) south of the school.

Note:

(a) Measurements are taken from the closest boundary of the construction zone to the closest edge of the land use, including school parking areas.

Sites 1, 7, 8, 11, 14, 15, 16, and 17 (Alternate)

Because no schools are located within a 0.25 mile of these sites, *no impact* would occur related to the emission or use of hazardous materials within 0.25 mile of a school during construction.

Impact Conclusion: No Impact

Sites 5, 6, 9, 10, 12, 13, and 18 (Alternate)

As shown on Table 5.17-3 (Schools within 0.25 Mile of a Proposed Well Facility Site Construction Area), Schools located within 0.25 mile of these sites include: Margaret Brown Elementary School (Site 5); Holy Angels Elementary School (Site 5); Hope Lutheran Elementary School (Sites 5 and 6); El Camino High School (Site 9); Alta Loma Middle School (Sites 9, 10, and 18 [Alternate]); R.W. Drake Preschool, Baden High School, and Los Cerritos Elementary School (Site 12); and South San Francisco High School (Sites 12 and 13).

Project construction activities are assumed by this analysis to include the use of hazardous materials such as fuels, lubricants, degreasers, paints, and solvents. These materials are commonly used during construction, are not acutely hazardous, and would be used in small quantities. Numerous laws and regulations ensure the safe transportation, use, storage, and disposal of hazardous materials (see Section 5.17.1 [Regulatory Framework]). Routine transport of hazardous materials to and from facility sites could result in an incremental increase in the potential for accidents. However, Caltrans and the CHP strictly regulate the transportation of hazardous materials and wastes, including container types and packaging requirements, as well as licensing and training for truck operators, chemical handlers, and hazardous waste haulers. Worker safety regulations cover hazards related to the prevention of exposure to hazardous materials and a release to the environment from hazardous materials use. Regulations and criteria for the disposal of hazardous materials mandate disposal at an appropriate landfill. Cal-OSHA also enforces hazard communication program regulations, which contain worker safety training and hazard information requirements, such as procedures for identifying and labeling hazardous substances, communicating hazard information related to hazardous substances and their handling, and preparation of health and safety plans to protect workers and employees.

These types of hazardous materials are commonly used at facilities such as gasoline stations and dry cleaners, and at construction areas. Although construction activities could result in the inadvertent release of small quantities of hazardous construction chemicals, a spill or release at a well facility construction area is not expected to endanger individuals at nearby schools given the nature of the materials and the small quantities that would be used. Therefore, because the SFPUC and its contractors would be required to comply with existing and future hazardous materials laws and regulations covering the transport, use, and disposal of hazardous materials, and because of the nature and quantity of the hazardous materials, the potential impact on schools related to the use of hazardous materials at these sites that are within 0.25 miles would be *less than significant.* In addition, although the impact is considered less than significant, the standard BMPs that would be implemented under the required erosion and sediment control plan (see Impact HY-1 in Section 5.16, Hydrology and Water Quality) would require specific preventative practices for safe storage and handling of chemicals, as well as secondary containment to contain a potential release. These standard BMPS would further serve to prevent and contain inadvertent releases of hazardous materials at construction sites.

Impact Conclusion: Less than Significant

Sites 2, 3, 4, 19 (Alternate), and the Westlake Pump Station

As shown on Table 5.17-3 (Schools within 0.25 Mile of a Proposed Facility Site Construction Area), Sites 2, 3, 4, and 19 (Alternate) are located within 0.25 miles of several schools, including: Ben Franklin Intermediate School (Sites 2, 3, 4, and Westlake Pump Station); Garden Village Elementary School (Sites 2, 3, 4); and R.W. Drake Preschool, Baden High School, and Los Cerritos Elementary (Site 19 [Alternate]).

Site 19 (Alternate) is located approximately 900 feet away from Baden High School, 1,250 feet away from Los Cerritos Elementary School, and immediately adjacent to R.W. Drake Preschool. As discussed previously, well facility construction activities are assumed by this analysis to include the use of hazardous materials such as fuels, lubricants, degreasers, paints, and solvents, which are commonly used during construction, are not acutely hazardous, and would be used in small quantities. The SFPUC and its contractors would be required to comply with existing and future hazardous materials laws and regulations covering the transport, use, and disposal of hazardous materials. These types of hazardous materials are commonly used at gasoline stations, dry cleaners, and other construction areas. Although construction activities could result in the inadvertent release of small quantities of hazardous construction chemicals, a spill or release at a well facility construction area is not expected to endanger individuals Baden High School or Los Cerritos Elementary School given the nature of the materials and the small quantities that would be used. Therefore, because of anticipated regulatory compliance and the nature and small quantity of the materials used and stored, an accidental spill or release would be unlikely to result in significant hazardous materials impacts on these schools. Therefore, the potential impact related to the use of hazardous materials within 0.25 miles of Baden High School and Los Cerritos Elementary School, would be *less than significant.*

However, several well facility site construction and staging areas would be located on, or immediately adjacent to, several schools. Site 2 is immediately adjacent to Garden Village Elementary School; Site 3 is located on Ben Franklin Intermediate School property; Site 4 is located on Garden Village Elementary School property; Westlake Pump Station is immediately adjacent to Ben Franklin Intermediate School; and Site 19 (Alternate) is immediately adjacent to R.W. Drake Preschool. Because of this close proximity, the potential for an adverse effect at Ben Franklin Intermediate School, Garden Village Elementary School, and R.W. Drake Preschool due to accidental spill or release of hazardous materials at Sites 2, 3, 4, 19 (Alternate), and the Westlake Pump Station could potentially be *significant*, even after considering the nature and quantity of the chemicals to be used and stored and compliance with laws and regulations.

However, implementation of Mitigation Measure M-HY-1 (Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan) and Mitigation Measure M-HZ-2c: (Hazardous Materials Management Plan) would reduce this potential hazardous materials impact to a *less-than-significant* level. While Mitigation Measure M-HY-1 is presented in Section 5.16, Hydrology and Water Quality, and primarily addresses water quality impacts, it also contains measures for controlling non-stormwater (i.e., equipment maintenance and servicing requirements and equipment fueling requirements), waste, and potential hazardous materials pollution, which would also reduce the potential for the accidental release of hazardous construction chemicals. The Erosion and Sediment Control Plan requires specific practices for the safe storage and handling of chemicals. The BMPs required to be in the plan include protection measures for the temporary on-site storage of diesel fuels or other hazardous materials used during construction, including requirements for secondary containment of a potential release and to prevent any such release from reaching an adjacent waterway or stormwater collection system. All equipment and materials storage would need to be routinely inspected for leaks and records maintained for documenting compliance with the storage and handling of hazardous materials. In addition, Mitigation Measure M-HZ-2c would require that the contractor prepare a Hazards Materials Management Plan to ensure proper handling of all hazardous substances that are used during construction. With the incorporation of these measures, the potential hazardous materials impact on Ben Franklin Intermediate School, Garden Village Elementary School, and R.W. Drake Preschool, due to emission or use of hazardous materials during construction of Sites 2, 3, 4, 19 (Alternate), and the Westlake Pump Station, would be *less than significant with mitigation*.

> ***Mitigation Measure M-HY-1: Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan (All Sites)***
> (See Impact HY-1 in Section 5.16, Hydrology and Water Quality, for description.)

> ***Mitigation Measure M-HZ-2c: Hazardous Materials Management Plan (All Sites)***
> (See Impact HZ-2 above for description.)

Impact Conclusion: Less than Significant with Mitigation

5.17.3.5 Operation Impacts and Mitigation Measures

Impact HZ-4. The Project would not create a hazard to the public or environment from the routine transport, use, or disposal of hazardous materials or accidental release of hazardous materials during operation. (Less than Significant)

The evaluation of impacts that follows discusses sites with no impacts first, followed by sites with less-than-significant impacts.

<u>Sites 2, 3, 4, 5 (Consolidated Treatment at Site 6), 7 (Consolidated Treatment at Site 6), 14, and 19 (Alternate)</u>

Because these well facilities would not store or use chemicals for disinfection or water treatment, accidental releases from stored chemicals would not occur. Therefore, *no impact* would occur relative to transport, use, or disposal of hazardous materials or an accidental release during operation of these sites.

Impact Conclusion: No Impact

Sites 1, 5 (On-site Treatment), 6, 7 (On-site Treatment), 8, 9, 10, 11, 12, 13, 15, 16, 17 (Alternate), 18 (Alternate), and the Westlake Pump Station

Attainment of water quality goals may require disinfection, treatment, or filtration prior to distribution of water into the regional water system or Partner Agency distribution systems. The primary chemicals needed at facility sites are sodium hypochlorite and ammonia for disinfection. Sodium hydroxide would be added if necessary to adjust the pH. Sodium fluoride would be required if the fluoride concentration in the blended water in the local water distribution system is below the respective water agency's identified fluoride levels (see Chapter 3, Project Description, Section 3.4.2.2 [Well Facility Types]).

As discussed in Chapter 3, Project Description, Section 3.4.2.2 (Well Facility Types), the chemical storage tanks would be placed on a pedestal and above a grate-covered chemical containment pit. The depth of the pit would be sized to provide 110 percent of the total storage volume in the event of a spill. A hatch on the grate would allow access for a sump pump to remove any spilled chemicals. Each tank is intended to provide a chemical storage capacity of 14 to 21 days (with an additional 15 percent safety factor). The proposed storage capacity allows for the frequency of chemical delivery to occur every two- to three weeks.

As described above, Project operation would involve regular transportation of hazardous materials. However, Caltrans and the CHP strictly regulate the transportation of hazardous materials and wastes, including container types and packaging requirements, as well as licensing and training for truck operators, chemical handlers, and hazardous waste haulers (see Section 5.17.1, Regulatory Framework). Vehicle and equipment inspection, shipment preparation, container identification, and shipping documentation are the responsibility of CHP, which conducts regular inspections of licensed transporters to assure regulatory compliance. Caltrans has emergency chemical spill identification teams at locations throughout the State that can respond quickly in the event of a spill.

The Uniform Fire Code, Article 80, includes specific requirements for the safe storage and handling of chemicals. These requirements are intended to reduce the potential for an accidental release and for mixing of incompatible chemicals. Design of chemical storage facilities at the well facilities and storage of chemicals for the Project at the Westlake Pump Station would comply with the current Uniform Fire Code requirements and other applicable federal, State, and local regulations, including design features (including noncombustible partitions, spill control features and separate secondary containment, as described above in Section 5.17.2.8 [Uniform Fire Code]) that would reduce the potential for a release of hazardous materials that could affect public health or the environment. The SFPUC would be required by the local CUPA agency (San Mateo County Health Department) to prepare an HMBP for the well facilities that store hazardous chemicals, as well as update the existing HMBP for the Westlake Pump Station facility to reflect the changes in hazardous materials storage.

The SFPUC would also be required to comply with existing and future hazardous materials laws and regulations covering the transport, use, and disposal of hazardous materials. In addition, the SFPUC would be required to incorporate legally mandated design features into the facilities and prepare HMBPs for chemical storage. Therefore, because the SFPUC would be required to comply with these laws and regulations that are designed to protect the public against potential impacts associated with the use of chemicals and accidental chemical releases, potential hazardous materials impacts during operation would be *less than significant*.

Impact Conclusion: Less than Significant

Impact HZ-5. The Project would not result in impacts from the emission or use of hazardous materials within 0.25 mile of a school during operation. (Less than Significant)

This impact discussion considers the potential for operational impacts due to the use of chemicals and other hazardous materials. Potential impacts related to operational pollutant emissions are discussed in Section 5.8, Air Quality, Impact AQ-6.

The evaluation of impacts that follows discusses sites with no impacts first, followed by sites with less-than-significant impacts.

<u>Sites 1, 2, 3, 4, Site 5 (Consolidated Treatment at Site 6), 6, 7, 8, 11, 14, 15, 16, 17 (Alternate), and 19 (Alternate)</u>

Because no schools would be located within a 0.25 mile of Sites 1, 6, 7, 8, 11, 14, 15, 16, and 17 (Alternate), *no impact* would occur related to emission or use of hazardous materials within 0.25 mile of a school during operation of these sites.

Sites 2, 3, 4, Site 5 (Consolidated Treatment at Site 6), and 19 (Alternate) would be located within a 0.25 mile of schools; however, these well facilities would not store or use chemicals for disinfection or water treatment. As a result, there would be *no impact* related to emission or use of hazardous materials within 0.25 mile of a school during operation of these sites.

Impact Conclusion: No Impact

<u>Sites 5 (On-site Treatment), 9, 10, 12, 13, 18 (Alternate), and Westlake Pump Station</u>

These well facilities, where chemicals would be stored on the site during Project operations, would be located within a 0.25 mile of schools and may store and use sodium hypochlorite, ammonia, sodium hydroxide, and sodium fluoride. The well facility building at Site 5 would be located approximately 475 feet from Holy Angels Elementary School, 1,200 feet from Hope Lutheran Elementary School, and 1,200 feet from Margaret Brown Elementary School. The well facility building at Site 9 would be located approximately 1,100 feet from El Camino High School and 1,275 feet from Alta Loma Middle School. Site 10 would be located approximately 950 feet from Alta Loma Middle School, and Site 18 (Alternate) would be located about 170 feet from the school. Site 12 would be located approximately 920 feet from Baden High School, 1,000 feet from South San Francisco High School, and 930 feet from Los Cerritos Elementary School. Site 13 would be located about 900 feet from South San Francisco High School. The parcel where the Westlake Pump Station is located is immediately adjacent to schoolyard athletic fields at Ben Franklin Intermediate School.

The potential for emissions of chemicals from an accidental release is discussed under Impact HZ-5. As stated there, incorporation of legally required design features and development of HMBPs for chemical storage would maintain the potential impact from increased use of chemicals and potential for accidental release at less-than-significant levels. This includes the potential for emission or use of hazardous materials within 0.25 mile of a school. Therefore, the potential for hazardous materials impacts related to emissions resulting from chemical storage and use to affect schools within 0.25 mile would also be *less than significant*.

Impact Conclusion: Less than Significant

Impact HZ-6. The Project would not result in a safety hazard for people residing or working in the vicinity of a public use airport. (Less than Significant)

The evaluation of impacts that follows discusses sites with no impacts first, followed by sites with less-than-significant impacts.

<u>Sites 1, 2, 3, 4, 5, 6, 7, 8, 17 (Alternate), and the Westlake Pump Station</u>

These sites are not located within an area covered by an airport land use plan or within two miles of a public airport. Therefore, *no impact* per this criterion would occur at these sites.

Impact Conclusion: No Impact

<u>Sites 9, 10, 11, 12, 13, 14, 15, 16, 18 (Alternate), and 19 (Alternate)</u>

These sites are located within an area covered by the San Mateo County Airport Land Use Plan for the SFO. Site 19 (Alternate) would be a well-only facility and surrounded by an 8-foot tall fence. The remaining well facilities would include buildings for treatment and/or filtration that would be a maximum of 15.5 feet above finished grade. As a result, the heights of the well facility buildings would be well below FAR Part 77 airport related height limitations and the land surrounding the well facility sites is almost entirely developed with urban uses that include structures as tall or taller than the proposed well facilities. In addition, the well facilities would not direct lights toward, or cause sunlight to be reflected toward, an aircraft, would not generate smoke or rising columns of air, would not attract large concentrations of birds, and would not cause electrical interference. Therefore, operation of the Project would not result in a safety hazard for people residing or working in the project area. As a result, this potential hazards impact would be *less than significant*.

Impact Conclusion: Less than Significant

Impact HZ-7: The Project would not expose people or structures to a significant risk of loss, injury, or death involving fires. (Less than Significant)

Exposure of people or structures to risk of loss, injury, or death involving fire could occur if the Project sites were located in areas susceptible to risk from fire. As discussed in the setting section, the SFPUC maintains Lake Merced as a nonpotable emergency water supply for the CCSF to be used for firefighting if no other sources of water are available (SFPUC 2011). Impact HY-10 in Section 5.16, Hydrology and Water Quality, discusses the effects of Project operations on Lake Merced lake levels.

<u>All Sites</u>

The facility sites would be located on urban land in zones designated as "Non-Fire Hazard" (CAL FIRE 2008). Therefore, the risk of fires from is considered very low and *no impact* would occur.

As discussed in Impact HY-10 in Section 5.16, Hydrology and Water Quality, water levels in Lake Merced would increase during wet and normal years and decrease during dry years ("Take Periods") (see Impact HY-10 in Section 5.16, Hydrology and Water Quality for an evaluation of the Lake Merced water level and modeled operational scenarios). Despite the increases and decreases in water levels in Lake Merced, water would be present in the lake and available for emergency use during Project operations. Therefore, impacts on the exposure of people or structures to fire risk due to changes in Lake Merced water levels would be *less than significant*.

Impact Conclusion: Less than Significant

5.17.3.6 Cumulative Impacts and Mitigation Measures

Impact C-HZ-1: Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to hazards and hazardous materials. (Less than Significant with Mitigation)

The geographic scope for the analysis of cumulative impacts relating to hazards and hazardous materials consists of each proposed GSR facility site (including the construction area for the well, the well facility, and the proposed or alternate pipelines) and the area surrounding the sites where an adverse effect could occur.

Construction

Use of Hazardous Materials

All of the cumulative projects listed in Table 5.1-3 (Project Considered for Cumulative Impacts) in Chapter 5, Environmental Setting, Impacts, and Mitigation Measures, Section 5.1, Overview, would result in the use, transport, and disposal of hazardous materials during construction within the cumulative impacts study area.

As described in Impact HZ-1, the GSR Project would have less-than-significant impacts associated with the potential to create a significant hazard, because the SFPUC and its contractors would be required to comply with the existing and future laws and regulations governing the use, transport, and disposal of hazardous materials.

Depending on the extent of overlap between the construction schedules for the projects listed in Table 5.1-3 (Project Considered for Cumulative Impacts), implementation of these projects together with the proposed GSR Project could result in a cumulative impact associated with increased hazards; however, each of the cumulative projects would need to comply with existing and future laws and regulations governing the hazardous materials, similar to the GSR Project. For this reason, the potential cumulative impact from the use, transport, and disposal of hazardous materials during construction would be less than significant. As a result, there would be no significant cumulative impact associated with increased hazards relative to the use, transport, or disposal of hazardous materials during construction to which the proposed Project would contribute (*less than significant*).

Accidental Release of Hazardous Chemicals or Building Materials

All of the cumulative projects listed in Table 5.1-3 (Projects Considered for Cumulative Impacts) in Chapter 5, Environmental Setting, Impacts, and Mitigation Measures, Section 5.1 (Overview), are likely to use fuels and other flammable materials during construction within the cumulative impacts study area. The PG&E Transmission Pipeline Replacement Project (cumulative project H) would be located 160 feet south of the pipeline construction area for GSR Site 11 in Chestnut Avenue and adjacent to the pipeline construction area for GSR Sites 12 and 19 (Alternate) along El Camino Real. In addition, a number of the cumulative projects would involve demolition of existing structures (e.g., the Centennial Village Project [cumulative project I], which is adjacent to the pipeline construction area for GSR Site 13, and would demolish the existing commercial businesses on the site), which could release asbestos, lead, or other hazardous building materials into the environment.

As identified above in Impact HZ-2, the GSR Project could cause significant impacts on workers and the environment, if accidental release of hazardous materials were to occur during construction or if contaminated soil or groundwater were encountered during construction. In addition, demolition of existing structures is proposed at GSR Sites 1 and 14, which could release hazardous building materials into the environment. Therefore, cumulative impacts related to accidental release of hazardous chemicals or building materials during construction could be *significant* and the GSR Project's contribution to this cumulative impact could be cumulatively considerable.

However, as discussed in Impact HZ-2, the GSR Project's impacts related to release of hazardous chemicals during construction would be reduced to *a less-than-significant* level with implementation of Mitigation Measure M-HZ-2a (Preconstruction Hazardous Materials Assessment), Mitigation Measure M-HZ-2b (Health and Safety Plan), and Mitigation Measure M-HZ- 2c (Hazardous Materials Management Plan),which require preconstruction hazardous materials assessments, site health and safety plans, and hazardous materials management plans. In addition, Mitigation Measure M-HY-1 (Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan), would require specific preventive practices for safe storage and handling of chemicals, as well as secondary containment to contain a potential release (see Impact HZ-2, above, for description). With regard to potential release of hazardous building materials from demolition, impacts at GSR Sites 1 and 14 would be *less than significant* due to compliance with applicable laws and regulations that provide procedures for identification and legal disposal of hazardous building materials. Therefore, with implementation of Mitigation Measure M-HZ-2a, Mitigation Measure M-HZ-2b, Mitigation Measure M-HZ-2c, and M-HY-1 at all GSR facility sites, the GSR Project's contribution to cumulative impacts related to compliance with hazards due to accidental release of hazardous chemicals or building materials during construction, would not be cumulatively considerable (*less than significant*).

Exposure of Schools to Hazardous Materials

The following cumulative projects listed in Table 5.1-3 (Projects Considered for Cumulative Impacts) would be located within 0.25 mile of a school that could be potentially affected by a proposed GSR facility site, and would be likely to use hazardous chemicals (e.g., fuels, lubricants, and paints) during construction:

- Cumulative project C, the Daly City "A" Street Well Replacement Project, would be within 0.25 mile of Holy Angels Elementary School, which would also be near GSR Site 5.
- Cumulative project D-2, the South San Francisco site for the Peninsula Pipelines Seismic Upgrade Project (PPSU), would be within 0.25 mile of Baden High School, which would also be near GSR Sites 12 and 19 (Alternate).
- Cumulative project E, Holy Cross Cemetery Expansion Project, would be within 0.25 mile of El Camino High School, which would also be near GSR Site 9.
- Cumulative project F, the Mission and McLellan Project, would be within 0.25 mile of El Camino High School and Alta Loma Middle School, both of which would also be near GSR Sites 9 and 10.
- Cumulative project H, the PG&E Transmission Pipeline Replacement Project, would be within 0.25 mile of Los Cerritos Elementary School, which would also be near GSR Sites 12 and 19 (Alternate).
- Cumulative project I, the Centennial Village Project, would be within 0.25 mile of South San Francisco High School, which would also be near GSR Site 13.

As identified in Impact HZ-3, this analysis presumes that some of the proposed GSR facilities would use hazardous materials such as fuels, lubricants, and paints during construction, which could cause a hazard at adjacent schools. Therefore, cumulative impacts related to an increased risk of exposure to hazardous materials to schools from use of hazardous chemicals during construction could be *significant*, and, for GSR Sites 2, 3, 4, 19 (Alternate), and the Westlake Pump Station, the GSR Project's contribution to this cumulative impact could be cumulatively considerable, given the close proximity of construction activities on or immediately adjacent to schools.

However, as discussed in Impact HZ-3, all of the above-listed projects would likely be using similar hazardous materials for the GSR Project (not acutely hazardous) and in non-industrial quantities. The transportation, use, and storage of these hazardous materials would be regulated by numerous laws and regulations, as described in Impact HZ-3. Additionally, for Sites 2, 3, 4, and 19 (Alternate), the GSR Project's impacts related to safety risks to nearby schools during construction would be reduced to *a less-than-significant* level with implementation of M-HY-1 (Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan) (see Impact HZ-3, above, for description) and M-HZ-2c (Hazardous Materials Management Plan). Implementation of these mitigation measures would ensure that specific preventive practices for safe storage and handling of chemicals, as well as procedures for secondary containment to contain a potential release, would be implemented during construction of the GSR Project. With implementation of these mitigation measures, the GSR Project's contribution to cumulative impacts related to an increased risk of exposure to hazardous materials to schools from use of hazardous chemicals during construction would not be cumulatively considerable *(less than significant)*.

Operations

Use of Hazardous Materials

Some of the cumulative projects listed in Table 5.1-3 (Projects Considered for Cumulative Impacts) may require the use, transport, and disposal of hazardous materials during operations. For example, the San Francisco Groundwater Supply Project (cumulative projects A-1 to A-6) and the Daly City "A" Street Well Replacement project (cumulative project C) could use, transport, and store common materials for water treatment if they include treatment facilities. The Mission & McLellan and Centennial Village development projects (cumulative projects F and I) could use, transport, and store common hazardous materials such as fuels, paints, and fertilizers for commercial operations, landscaping, and site maintenance.

As described in Impact HZ-4, the GSR sites with treatment facilities would use and store common materials for water treatment, and be required to incorporate legally required design features and HMBPs for chemical storage. These legal requirements are designed to protect the public against potential impacts associated with the use of chemicals and accidental chemical releases. Therefore, the Project would have *less-than-significant* impacts associated with the potential to create a significant hazard, because the SFPUC would be required to comply with the existing and future laws and regulations governing the use, transport, and disposal of hazardous materials.

For the projects listed in Table 5.1-3 (Projects Considered for Cumulative Impacts), implementation of these projects together with the proposed GSR Project could result in a cumulative impact associated with increased hazards; however, each of the cumulative projects would need to comply with the existing and future laws and regulations governing hazardous materials, similar to the GSR Project. For this reason, the potential cumulative impact from the use, transport, and disposal of hazardous materials during operations would be *less than significant*. As a result, there would be no significant cumulative impact associated with increased hazards relative to the use, transport, or disposal of hazardous materials during operations *(less than significant*).

Exposure of Schools to Hazardous Materials

Some of the cumulative projects listed in Table 5.1-3 (Projects Considered for Cumulative Impacts) would be likely to use hazardous chemicals (e.g., paints, fertilizers) during operations. For example, the San Francisco Groundwater Supply Project (cumulative projects A-1 to A-6) and the Daly City "A" Street Well Replacement project (cumulative project C) could use, transport, and store common materials for water treatment if they include treatment facilities. The Mission & McLellan and Centennial Village development projects (cumulative projects F and I, respectively) could use, transport and store common hazardous materials such as fuels, paints, and fertilizers for commercial operations, landscaping, and site maintenance. Some of these cumulative projects would also be located within 0.25 mile of a school that could also be potentially affected by a proposed GSR facility site (see list under Exposure of Schools to Hazardous Materials during construction).

As identified in Impact HZ-5, some of the proposed GSR sites where treatment facilities would be built would store hazardous materials such as sodium hydroxide (for pH adjustment) and sodium hypochlorite (for disinfection) for use during operations. Such storage and use of these common water treatment chemicals would have less-than-significant impacts associated with the accidental release of chemicals near schools, because the storage amounts would be minimal (i.e., only enough for two to three weeks' supply would be stored on site when wells are operating), and the SFPUC would be required to comply with the existing and future laws and regulations governing the storage, use, transport, and disposal of such hazardous materials.

For the projects listed in Table 5.1-3 (Projects Considered for Cumulative Impacts), operation of these projects together with the proposed GSR Project could nevertheless result in a cumulative impact associated with increased risk of accidental release near schools; however, each of the cumulative projects would need to comply with the existing and future laws and regulations governing hazardous materials, similar to the GSR Project. For this reason, the potential cumulative impact from the storage, use, transport, and disposal of these water treatment chemicals during operations would be *less than significant*. As a result, there would be no significant cumulative impact associated with increased hazards relative to the use, transport, or disposal of hazardous materials during operations (*less than significant*).

Safety Hazard near an Airport

Of the cumulative projects listed in Table 5.1-3 (Projects Considered for Cumulative Impacts), cumulative projects D-1, and E through I would also be located within lands subject to the San Mateo County Airport Land Use Plan (ALUP). The Holy Cross Expansion Project and the California Water Service Company Water Well Replacement Project (cumulative projects E and G, respectively) are cemetery expansion and well replacement projects. The PPSU Colma site (cumulative project D-1) and PG&E Transmission Pipeline Replacement Project (cumulative project H) are infrastructure improvement projects that would not include new aboveground features. The Mission & McLellan Project (cumulative project F) has a maximum height of 50 feet above grade (Allison Knapp Wollam Planning & Environmental Consulting 2010). These cumulative projects would not likely be inconsistent with air space restrictions due to height, although lighting impacts are unknown. It is unknown if the Centennial Village Project (cumulative project I) would have elements that would be inconsistent with air space restrictions contained in the ALUP. As identified in Impact HZ-6, some of the proposed GSR sites (GSR Sites 9 through 16, 18 [Alternate], and 19 [Alternate]) would also be located within lands subject to the San Mateo County ALUP. However, the proposed GSR facilities would have *less-than-significant* impacts on safety hazards near an airport, because the GSR Project would not exceed FAR Part 77 airport-related height limitations. In addition, the well facilities would not direct lights toward, or cause sunlight to be reflected toward, an aircraft, and would not generate smoke or rising columns of steam.

For the projects listed in Table 5.1-3 (Projects Considered for Cumulative Impacts), operation of these projects together with the proposed GSR Project could result in a cumulative impact associated with increased safety hazards near SFO because they could include new lighting or facilities that may be inconsistent with air space restrictions contained in the ALUP, such as airport-related height limitations, directing lights toward, or cause sunlight to be reflected toward an aircraft, or generate smoke or rising columns of steam. The cumulative impact would, therefore, be *significant*. However, as described in Impact HZ-6, the GSR Project well facility buildings would be well below FAR Part 77 airport-related height limitations, and the land surrounding the facility sites is almost entirely developed with urban uses that include structures as tall or taller than the proposed well facilities. Therefore, the GSR Project's contribution to potentially significant cumulative impacts from increased safety hazards near an airport would not be cumulatively considerable *(less than significant)*.

Exposure of People or Structures to Fire Risk

Some of the cumulative projects may be located on land designated as moderate fire hazard severity zones. None of the cumulative projects would be located on land designated as high to very high fire hazard severity zones. The GSR Project would be located in urban land in zones designated as "Non-Fire Hazard" and the risk from fire is considered very low (CAL FIRE 2008). Therefore, the GSR Project and the cumulative projects would not combine to create a significant cumulative effect related to risk from fire *(less than significant)*.

Additionally, the San Francisco Groundwater Supply Project (cumulative project A-1 through A-6) and the Vista Grande Drainage Basin Improvement Project (cumulative project B) could affect water levels in Lake Merced. Lake Merced water may be used for firefighting purposes in emergency situations, and a reduction of water levels could impact the availability water for firefighting purposes. However, water would still be present in the lake and available for emergency use even with implementation of the cumulative projects. Therefore, the anticipated cumulative impact would be *less than significant.*

5.18 MINERAL AND ENERGY RESOURCES

This section analyzes the proposed Project's potential impacts on the use of non-renewable mineral and energy resources, as well as on water use, and the potential for Project implementation to adversely affect the availability of these resources. The study area for mineral and energy resources includes the facility sites and the nearby areas.

5.18.1 Setting

5.18.1.1 Mineral Resources

In accordance with the Surface Mining and Reclamation Act of 1975 (SMARA) (discussed below in Section 5.18.2.2 [State Regulations]), the California Department of Conservation, Division of Mines and Geology, currently known as the California Geological Survey (CGS), has mapped nonfuel mineral resources of the State to show where economically significant mineral deposits are either present or likely to occur based on the best available scientific data. These resources have been mapped using the California Mineral Land Classification System, which includes the following four Mineral Resource Zones (MRZs):

- **MRZ-1.** Areas where adequate information indicates that no significant mineral deposits are present, or where it is judged that little likelihood exists for their presence.
- **MRZ-2.** Areas where adequate information indicates that significant mineral deposits are present, or where it is judged that a high likelihood exists for their presence.
- **MRZ-3.** Areas containing mineral deposits, the significance of which cannot be evaluated.
- **MRZ-4.** Areas where available information is inadequate for assignment to any other zone.

The study area is mapped as MRZ-1, which indicates that the study area does not, or is unlikely to contain, significant mineral resources (CGS 1987, 1996).

5.18.1.2 California's Electricity Supply

California's electricity is generated by a number of sources, including natural gas (46 percent), coal (18 percent), large hydroelectric plants (11 percent), and nuclear (14 percent) (CEC 2009). The remaining 11 percent is supplied from geothermal, biomass, small hydroelectric, wind, and solar sources (CEC 2009). Established in 2002 under Senate Bill 1078 (SB 1078) and accelerated in 2006 under Senate Bill 107 (SB 107), California's Renewable Portfolio Standard (RPS) requires electric corporations to increase procurement from eligible renewable energy resources by at least one percent of their retail sales annually, until they reached 20 percent by 2010. On September 15, 2009, former Governor Schwarzenegger signed Executive Order S-21-09 directing the California Air Resources Board (CARB) to adopt regulations increasing California's RPS to 33 percent by 2020. In 2010, the three largest investor-owned utilities, including the Pacific Gas and Electric Company (PG&E), had reached 17.9 percent (CPUC 2011).

5.18.1.3 Current Energy Providers

SFPUC Power Enterprise

The San Francisco Public Utilities Commission (SFPUC) Power Enterprise would provide electrical power service for the Project facilities, primarily from power generated by the SFPUC's hydroelectric facilities in the Hetch Hetchy system. The system includes 401 megawatts (MW) of hydroelectric power generation plants on the Tuolumne River and 150 miles of high-voltage transmission lines that carry this power to California's electricity grid at Newark, California, where the Hetch Hetchy power system is linked to California's electricity grid. Energy production varies by season and by year depending on hydrologic conditions. The long-term annual average production is approximately 1.7 billion kilowatt-hours (kWh); historical production has ranged from a low of 1.2 billion kWh per year to a high of 2.2 billion kWh per year (SFPUC 2002). The total energy usage of existing facilities within the Water System Improvement Program (WSIP) regions is nearly 44 million kWh, less than four percent of the historical low production rate of the regional water system and less than three percent of the long-term annual average production rate (incorporated by reference from the WSIP Program EIR, Chapter 4, WSIP Facility Projects – Setting and Impacts, Section 4.15, Energy Resources, Section 4.15.1 Setting [San Francisco Planning Department 2008]).

The SFPUC Power Enterprise provides electricity to all City and County of San Francisco (CCSF) facilities (including tenants), including the San Francisco International Airport and its tenants, and would supply power for the proposed Project. The SFPUC Power Enterprise also sells electricity to Norris Industries (a federal defense contractor), provides electricity for the municipal and agricultural pumping loads of the Modesto and Turlock Irrigation Districts, and sells electricity to other public agency wholesalers. While the quantity of power produced exceeds San Francisco's municipal power needs on an annual basis, the CCSF must supplement its power sources to meet municipal demand and its contractual obligations during the summer and fall months, at which time power generation is reduced so that water can be stored. The SFPUC Power Enterprise load profile is relatively flat (i.e., not dramatically higher in the summer), because it is not driven by air conditioning use.

Pacific Gas and Electric Company

PG&E provides natural gas and electricity to most of Northern California. It provides the SFPUC Power Enterprise with transmission and distribution services from Newark, California, to points west, pursuant to an Interconnection Agreement regulated by the Federal Energy Regulatory Commission (FERC). Under this agreement, PG&E transmits and distributes electricity to the SFPUC Power Enterprise customers and would provide power distribution services for the proposed Project.

5.18.1.4 Existing Energy Use and Distribution

The SFPUC annual energy demand for operation of the regional water system was approximately 35 million kWh in 2009 when the system delivered 219 million gallons per day (mgd); none of this energy demand came from pumping groundwater.

Based on the volume of existing groundwater supply of 6.8 mgd, the Partner Agencies' annual energy demand is estimated to be approximately 16 million kWh[1] to pump, treat and distribute water from their existing groundwater facilities (see Appendix I [Calculations for GSR Energy Use Impacts]).

Because the proposed Project affects energy demand of the regional water system as well as the Partner Agencies' groundwater systems, existing energy use collectively is estimated to be 51 million kWh.[2]

5.18.2 Regulatory Framework

5.18.2.1 Federal Regulations

National Energy Policy Act of 2005

The National Energy Policy Act of 2005 sets equipment energy-efficiency standards and seeks to reduce reliance on nonrenewable energy resources and provide incentives to reduce current demand on these resources. For example, under the Act, consumers and businesses can attain federal tax credits for purchasing fuel-efficient appliances and products, including hybrid vehicles, constructing energy-efficient buildings, and improving the energy efficiency of commercial buildings. Additionally, tax credits are available for the installation of qualified fuel cells, stationary microturbine power plants, and solar power equipment.

5.18.2.2 State Regulations

Surface Mining and Reclamation Act of 1975

In accordance with SMARA and as discussed above in Section 5.18.1.1 (Mineral Resources), the State has established the California Mineral Land Classification System to help identify and protect mineral resources in areas that are subject to urban expansion or other irreversible land uses that would preclude mineral extraction. Protected mineral resources include construction materials, industrial and chemical mineral materials, metallic and rare minerals, and nonfluid mineral fuels.

---

[1] Energy demand for the Partner Agencies' groundwater supply systems was estimated by multiplying the volume of Partner Agency pumping (6.8 mgd) by the projected unit energy demand for the proposed Project's new well facilities (6.4 million kWh per mgd). This calculation is appropriate, because the Partner Agencies are likely using the same general type of equipment and pumping from the same groundwater basin as the proposed new well facilities. However, the calculation is expected to overestimate energy demand somewhat, because some of the Partner Agencies are pumping from shallower aquifers, and the unit energy demand of the proposed new well facilities is based on design loads rather than actual loads (e.g., the new well facilities would not actually operate 24 hours a day in a dry year, but the calculation of the unit energy demand makes this assumption). See Appendix I (Calculations for GSR Energy Use Impacts).

[2] Existing energy use of 51 million kWh is the sum of regional water system 2009 annual energy demand of approximately 35 million kWh, plus the Partner Agencies' 2009 annual energy demand of approximately 16 million kWh.

The Surface Mining and Reclamation Act of 1975 (Chapter 9, Division 2, Section 2710 et seq. of the Public Resources Code) requires the State Mining and Geology Board to adopt State policies for reclaiming mined lands and conserving mineral resources. Title 24 of the California Code of Regulations, Division 2, Chapter 8, Subchapter 1, contains these policies.

2005 California Energy Action Plan II and 2008 Update

The Energy Action Plan II, and subsequent update in 2008, is the State's principal energy planning and policy document (CEC and CPUC 2005, 2008). The plan continues the goals of the original Energy Action Plan, describes a coordinated implementation plan for State energy policies, and identifies specific action areas to ensure that California's energy is adequate, affordable, technologically advanced, and environmentally sound. In accordance with this plan, the first-priority actions to address California's increasing energy demands are energy efficiency and demand response (i.e., reduction of customer energy usage during peak periods in order to address system reliability and support the best use of energy infrastructure). Additional priorities include the use of renewable sources of power and distributed generation (i.e., the use of relatively small power plants near or at centers of high demand). To the extent that these actions are unable to satisfy the increasing energy and capacity needs, clean and efficient fossil-fired generation is supported. At the beginning of 2008, the California Energy Commission (CEC) and California Public Utilities Commission (CPUC) determined it was not necessary or productive to create a new Energy Action Plan. The State's energy policies have been significantly influenced by the passage of Assembly Bill 32, the California Global Warming Solutions Act of 2006. So rather than produce a new Energy Action Plan, the CEC and CPUC prepared an "update" that examines the State's ongoing actions in the context of global climate change.

The Energy Action Plan II includes the following energy efficiency actions specific to water supply systems: Identify opportunities and support programs to reduce electricity demand related to the water supply system during peak hours, as well as opportunities to reduce the energy needed to operate water conveyance and treatment systems. Because much of electricity demand growth is expected to be met by increases in natural-gas-fired generation, reducing consumption of electricity and diversifying electricity generation resources are significant elements of plans to reduce natural gas demand.

Building Energy Efficiency Standards

The Energy Efficiency Standards for Residential and Nonresidential Buildings, as specified in Title 24, Part 6, of the California Code of Regulations (CCR), were established in 1978 in response to a legislative mandate to reduce California's energy consumption. The standards are updated periodically to allow consideration and possible incorporation of new energy efficiency technologies and methods. The CEC adopted the 2008 Standards on April 23, 2008, and the Building Standards Commission approved them for publication on September 11, 2008. The 2008 Non-residential Compliance Manual was adopted January 14, 2009. The new standards went into effect January 1, 2010, and were updated again in 2011.

5.18.2.3 Local

San Francisco Sustainability Plan

The San Francisco Board of Supervisors endorsed the San Francisco Sustainability Plan in 1997, although the Board has not committed the CCSF to perform the actions addressed in the plan. The plan addresses a broad scope of environmental issues such as air quality, human health, biodiversity, and solid waste management to promote sustainability. The major energy goals expressed in the plan are: reduction of overall power use through maximizing energy efficiency; maintaining an energy supply based on renewable, environmentally sound resources; elimination of climate-changing and ozone-depleting emissions, and toxics associated with energy production and use; and basing energy decisions on the goal of creating a sustainable society (San Francisco 1997).

San Francisco Electricity Resource Plan

The 2002 Electricity Resource Plan for San Francisco presented the initial action plan to meet the City's growth in demand for electricity using renewable energy resources. Goals included in this plan were: assure reliable power; maximize energy efficiency; develop renewable power; increase local control; affordable electric bills; improve air quality; support environmental justice; and promote economic opportunities. One of the primary goals of the plan, to facilitate the shutdown of two of the older fossil-fueled power plants located in the City on Hunters Point and in Potrero Hill, was achieved in 2006 and 2011, respectively (SFPUC 2002). The *2011 Update of the San Francisco Electricity Resource Plan* reaffirms the on-going goals of the 2002 Electricity Resource Plan and details the next steps to help San Francisco achieve its goal of generating all of its energy needs from renewable and zero-greenhouse gas (GHG) electric energy sources by 2030. The updated plan is designed to cover all electrical energy needs in San Francisco, not just the electrical energy needs provided by the SFPUC to serve municipal facilities. The updated plan proposes three broad strategies to reduce GHG emissions from electricity:

- Empower San Francisco citizens and businesses to cost-effectively reduce GHG emissions associated with their own electric energy usage;
- Increase the amount of zero-GHG electricity supplied to the City's customers from the wholesale energy market; and
- Continue and expand the SFPUC electric service to guarantee reliable, reasonably-priced and environmentally sensitive service to its customers.

The 2011 Electricity Resource Plan includes recommendations for implementation of each of these strategies (SFPUC 2011).

5.18.3 Impacts and Mitigation Measures

5.18.3.1 Significance Criteria

For the purposes of this EIR, the Regional Groundwater Storage and Recovery Project would have a significant effect on minerals and energy resources if it were to:

- Result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the State.
- Result in the loss of availability of a locally important mineral resource recovery site delineated on a local general plan, specific plan, or other land use plan.
- Encourage activities which result in the use of large amounts of fuel, water, or energy, or use these in a wasteful manner.

5.18.3.2 Approach to Analysis

This analysis evaluates the potential Project-related loss of availability of locally or regionally important mineral resources based on mapping conducted under the CGS Mineral Land Classification System. Impacts related to the loss of mineral resources would be considered significant if construction activities would make known mineral resources temporarily unavailable, or if the construction of new facilities would make these resources permanently unavailable.

This analysis also evaluates the use of energy resources (e.g., fuel and electricity) and the use of water associated with the construction and operation of the Project. For construction, the analysis considers whether construction activities would use large amounts of fuels, water, or energy, and whether they would be used in a wasteful manner. For energy, water, and fuel used during operation and maintenance, the analysis identifies the average annual increase in energy and fuel use that would occur with implementation of the Project to determine whether large amounts would be used and whether they would be used in a wasteful manner.

Natural gas would not be required for Project construction or operation and is not discussed further in this section.

With respect to water use, the Project would supply, treat, and distribute groundwater for use during a dry year. The additional water supply would supplant an existing source of water, but it would not increase demand (as, for example, a residential project would). Project construction techniques, such as watering exposed surfaces, would not result in the wasteful use of water or encourage activities using large amounts of water given that a water truck has a limited volume and it is to the benefit of the contractor not to water the site excessively. For these reasons, water usage is not discussed further in this section.

Areas of No Project Impact

The Project would not result in impacts related to the first and second significance criteria. These criteria are not discussed further in this section for the following reasons:

Result in the loss of availability of a known mineral resource of value to the region or State. As noted in Section 5.18.1.1 (Mineral Resources), the study area is mapped as MRZ-1, which means that no known mineral resources pursuant to SMARA were identified within the study area (CGS 1987, 1996). Therefore, the Project would not result in the loss of known mineral resources or make them inaccessible. As a result, this significance criterion would not be applicable to the Project.

Result in the loss of availability of a locally important mineral resource recovery site. As noted in Section 5.18.1.1 (Mineral Resources), the study area is mapped as MRZ-1, which means that no known mineral resources pursuant to SMARA were identified within the study area (CGS 1987, 1996). There are no locally important mineral resource recovery sites identified on a local general plan, specific plan, or other land use plan within the Project area (Colma 1999; Daly City 1987; Millbrae 1998; San Bruno 2009; San Mateo County 1986a, 1986b; South San Francisco 1999). Therefore, the Project would not impact the accessibility of a locally important mineral resource recovery site. As a result, this significance criterion would not be applicable to the Project.

5.18.3.3 Impact Summary

Table 5.18-1 (Summary of Impacts – Mineral and Energy Resources) provides a summary of potential impacts to energy resources and significance determinations.

TABLE 5.18-1
Summary of Impacts – Mineral and Energy Resources

Impact ME-1: The Project would not encourage activities that result in the use of large amounts of fuel and energy in a wasteful manner during construction.	**Impact ME-2: The Project would not encourage activities that result in the use of large amounts of fuel and energy in a wasteful manner during operation.**	**Impact C-ME-1: Construction and operation of the proposed Project would not result in a cumulatively considerable contribution to cumulative impacts related to mineral and energy resources.**
LS All Sites	LS All Sites	LS All Sites

Notes:

LS = Less than Significant

LSM = Less than Significant with Mitigation

5.18.3.4 Construction Impacts and Mitigation Measures

Impact ME-1: The Project would not encourage activities that result in the use of large amounts of fuel and energy in a wasteful manner during construction. (Less than Significant)

<u>All Sites</u>

Construction of the Project would require the use of fossil fuels (primarily gas, diesel, and motor oil) for a variety of activities, including well drilling, excavation, grading, demolition, generator use, and vehicle travel. The precise amount of construction-related energy consumption is uncertain. However, given the nature and scale of Project construction (i.e., potentially up to 19 wells drilled, with operation of only 16), construction would not require a large amount of fuel or energy usage because of the moderate number of construction vehicles and equipment, worker trips, and truck trips that would be required for a project of this scale (see Table 3-8 [Estimated Daily Worker and Construction Equipment Trips for Well Facilities Construction], in Chapter 3, Project Description, Section 3.5.1.2 [Construction Methods for Well Facilities]). Therefore, Project construction would not encourage activities that would result in the use of large amounts of fuel and energy in a wasteful manner. The impact would be *less than significant.*

Impact Conclusion: Less than Significant

5.18.3.5 Operation Impacts and Mitigation Measures

Impact ME-2: The Project would not encourage activities that result in the use of large amounts of fuel and energy in a wasteful manner during operation. (Less than Significant)

<u>All Sites</u>

The production of groundwater requires electricity to pump the groundwater from the wells, convey it to a water treatment system, treat the groundwater, and convey the treated water to the potable water distribution system. The amount of energy required would depend on the efficiency of the pumping equipment, the depth to groundwater, the distance to the treatment facility, the type of treatment required, and the distance to the distribution system. The proposed Project, during dry years, would increase energy demand associated with the pumping of accumulated water in the southern portion of the Westside Groundwater Basin; dry years are projected to occur in approximately 23 percent of the years (see Appendix I [Calculations for GSR Energy Use Impacts]). The proposed well facilities have been designed and sited so that wells would be close to treatment systems and close to existing distribution systems (the local distribution systems of the Partner Agencies and the regional water system), which would support an efficient use of energy (see Chapter 3, Project Description, Section 3.4.2 [Production Wells and Associated Facilities]). In accordance with the WSIP Greenhouse Gas Reduction Actions, the SFPUC would consult with its Power Enterprise's Energy Efficiency Group to incorporate applicable energy efficiency measures into the Project design, would attempt to maximize efficiency by exceeding Title 24 minimum requirements by at least 20 percent, and would attempt to meet or exceed LEED Silver certification. At a minimum, the proposed well facilities would be designed to meet California's energy efficiency standards outlined in Title 24 of the California Code of Regulations (see Chapter 3, Project Description, Section 3.7 [Greenhouse Gas Reduction Actions] and Section 3.4.2.2 [Well Facility Types]).

The proposed Project's energy demand would be the result of three operational components as discussed in Chapter 3, Project Description, Section 3.8 (Operations and Maintenance) and as shown on Figure 3-2 (Source of Proposed Water Supply for Partner Agencies). This includes operation of the new well facilities and pump station, operation of the Partner Agency wells, and operation of the regional water system. Each of these operational components is discussed below; refer to Appendix I (Calculations for GSR Energy Use Impacts) for additional information and assumptions.

New Well Facilities and Westlake Pump Station Upgrade

Most of the Project's energy demand would be due to pumping at the new wells; however, a small amount of energy would be required to operate the well facility buildings and treatment systems. The energy demand from the new well facilities and the Westlake Pump Station upgrade from pumping 7.2 mgd during a dry year (i.e., Take Year) would be approximately 17 million kWh (see Appendix I [Calculations for GSR Energy Use Impacts]). This would be the maximum annual demand, since the pumping volume would be greatest and the groundwater levels would be lowest during a dry year, thereby requiring more energy to pump the water to the surface (see Appendix I [Calculations for GSR Energy Use Impacts]). In other words, a greater volume of water would be pumped a greater distance.

Energy demand at the proposed well facilities in normal or wet years (i.e., Put or Hold Years) would be negligible, as the well pumps would only be turned on approximately four hours per month to exercise the wells and keep them from fouling (see Chapter 3, Project Description, Section 3.8.3 [Maintenance]).

Taking into account the projected frequency of dry, normal, and wet years, the long-term average annual energy demand of the proposed new well facilities and the Westlake Pump Station upgrade would be approximately four million kWh (see Appendix I [Calculations for GSR Energy Use Impacts]).

Partner Agency Wells

During dry years (i.e., Take Years), and in accordance with the proposed Operating Agreement (see Chapter 3, Project Description, Section 3.8.1 [Operating Agreement]), Partner Agency pumping would be 6.9 mgd, a slight increase over existing pumping, as calculated over a five-year averaging period; the estimated annual energy demand would increase only slightly.

During wet and normal years when the SFPUC Storage Account is full (i.e., Hold Years), the Partner Agencies could pump groundwater at the 6.9 mgd rate, as calculated over a five-year averaging period; the estimated annual energy demand would increase over the existing demand (at the 6.8 mgd pumping rate) only slightly. Under the proposed Operating Agreement, the Partner Agencies would be allowed to increase pumping by 10 percent over the 6.9 mgd, or a total of 7.6 mgd for a short period, but the five-year average pumping rate would still need to be maintained at 6.9 mgd. Therefore, any increased energy demand due to this possibility of short-term increased pumping by the Partner Agencies would be offset by decreased energy demand from reduced pumping required to maintain the 6.9 mgd five-year average pumping rate.

During normal and wet years when the SFPUC Storage Account is not full (i.e., Put Years), pumping by the Partner Agencies would be reduced substantially to 1.4 mgd. Estimated annual energy demand for the Partner Agencies' well facilities would decrease accordingly from 16 to 3 million kWh in normal and wet years (see Appendix I [Calculations for GSR Energy Use Impacts]).

Taking into account the projected frequency of dry, normal, and wet years, the long-term average annual energy demand of the Partner Agency's well facilities would decrease by approximately four million kWh (see Appendix I [Calculations for GSR Energy Use Impacts]).

Regional Water System

Under the proposed Project and in accordance with the proposed Operating Agreement, the SFPUC would decrease surface water deliveries to retail and wholesale customers by 7.2 mgd during dry years (i.e., Take Years), when water supply from groundwater would increase, resulting in energy savings to the regional water system of approximately one million kWh (see Appendix I [Calculations for GSR Energy Use Impacts]).

During normal and wet years when the SFPUC Storage Account is full (i.e., Hold Years), no changes would occur to deliveries from the regional water system due to the Project.

However, during normal and wet years when the SFPUC Storage Account is not full (i.e., Put Years), the SFPUC would increase surface water deliveries to the Partner Agencies by 5.5 mgd, when groundwater pumping would decrease to allow the southern portion of the Westside Groundwater Basin to recharge naturally. This increase in surface water deliveries would result in additional energy use by the regional water system of approximately one million kWh (see Appendix I [Calculations for GSR Energy Use Impacts]).

Taking into account the projected frequency of dry, normal, and wet years, the long-term average annual energy demand for the regional water system would not change substantially from the existing energy demand as a result of the proposed Project (see Appendix I [Calculations for GSR Energy Use Impacts]).

New Well Facilities, Partner Agency Wells, and Regional Water System

Thus, the collective change in energy demand of the new well facilities and Westlake Pump Station (increase of four million kWh), the Partner Agencies' wells (decrease of four million kWh) and the regional water system (no change) would be negligible, and the proposed Project would not cause a substantial increase in energy use on a long-term basis (see Appendix I [Calculations for GSR Energy Use Impacts]).

The Project also would use a small amount of fuel for worker trips to perform routine equipment checks at each well facility site. Each well station would be visited daily when wells are operating. During normal and wet years, the wells normally would be turned off, but regular exercising would be conducted. At these times, the wells would be visited on a weekly basis or at a frequency determined by on-site conditions (see Chapter 3, Project Description, Section 3.8.3 [Maintenance]).

Impact Conclusion

Therefore, because (1) the necessary power for the Project is already produced and distributed through existing infrastructure, (2) the Project is designed to be energy efficient and not waste energy, and (3) the proposed Project would not increase energy demands, the potential impacts associated with energy resources during operation of the Project would be *less than significant*. The energy resources that would be consumed by the Project would be for the public benefit and would not be wasteful, because the Project serves to increase water delivery reliability, meet customer water supply needs, and increase regional operational flexibility.

Impact Conclusion: Less than Significant

5.18.3.6 Cumulative Impacts and Mitigation Measures

Impact C-ME-1: Construction and operation of the proposed Project would not result in a cumulatively considerable contribution to cumulative impacts related to mineral and energy resources. (Less than Significant)

The geographic scope for the analysis of potential cumulative mineral and energy resources impacts consists of the proposed GSR facility sites, and the general vicinity (for mineral resources), and service area for the SFPUC Power Enterprise (for energy resources), as described in Section 5.18.1.3 (Current Energy Providers).

Construction

Mineral Resources

Because construction of the GSR Project would not result in Project-specific impacts related to mineral resources, implementation of the Project would not result in cumulative impacts to these resources (*no impact*).

Energy Resources

The cumulative projects listed in Table 5.1-3 (Projects Considered for Cumulative Impacts) and the proposed GSR Project (see Impact ME-1) would all use energy during construction, which could result in a *significant* cumulative energy impact. However, the GSR Project's contribution to this cumulative impact would not be cumulatively considerable, given that construction of the Project as proposed would use a small amount of fuel and energy in an efficient manner for the public benefit. Therefore, the GSR Project's contribution to a significant cumulative impact on energy resources would not be cumulatively considerable (*less than significant*).

Operation

Mineral Resources

Because operation of the GSR Project would not result in Project-specific impacts related to mineral resources, implementation of the Project would not result in cumulative impacts to these resources (*no impact*).

Energy Resources

Most of the cumulative projects listed in Table 5.1-3 (Projects Considered for Cumulative Impacts) would result in incremental increases in energy demand during long-term operation. The San Francisco Groundwater Supply Project (cumulative projects A-1 to A-6) would use the SFPUC Power Enterprise electricity to pump up to 4 mgd of groundwater for potable water supply. Expansion of the Holy Cross Cemetery (cumulative project E) would increase energy use to pump an additional 0.04 mgd of groundwater for cemetery operations. The Mission & McLellan Project (cumulative project F) would increase energy demand to supply power to 20 new condominium units. Lastly, the Centennial Village Project (cumulative project I) would increase energy demand with a new shopping center and 132 new apartment units.

As described in Impact ME-2, the GSR Project would have *less-than-significant* impacts on energy demand during operation, because it would not increase the long-term use of energy, it would not use energy in a wasteful manner, and the long-term energy demand for maintenance would be small.

Nevertheless, implementation of the proposed GSR Project, together with the cumulative projects listed in Table 5.1-3 (Projects Considered for Cumulative Impacts), could result in a *significant* cumulative impact on energy use. However, as discussed above, operation of the proposed GSR Project would not increase energy use in the long-term and would not be wasteful of energy resources. As a result, the GSR Project's contribution to a cumulative impact on energy resources would not be cumulatively considerable (*less than significant*).

5.19 AGRICULTURE AND FOREST RESOURCES

This section describes existing agricultural and forest resources at each facility site and analyzes the potential for Project construction or operation to affect such resources through displacement or conversion of these uses.

5.19.1 Setting

The proposed Project would be located in northern San Mateo County in unincorporated San Mateo County, the Town of Colma, and the cities of Daly City, South San Francisco, San Bruno, and Millbrae. The proposed Project would be located in areas characterized primarily by developed urban/suburban landscapes, and within the Golden Gate National Cemetery and Lake Merced Golf Club. No proposed well facility sites would be located in areas zoned for, or used for, agricultural or forestry purposes. The study area for potential impacts to agriculture and forest resources is the construction area boundary of the individual facility sites.

5.19.1.1 Agricultural Resources

Farmland Classifications

Farmland Mapping and Monitoring Program

The California Natural Resources Agency's Department of Conservation (CDC), Division of Land Resource Protection, maps important farmlands throughout California. Important farmlands are classified into the categories listed below on the basis of soil conditions (their suitability for agriculture) and current land use.

- **Prime Farmland.** This category represents farmland with the best combination of physical and chemical characteristics for long-term agricultural production. It has the soil quality, growing season, and moisture supply needed to produce sustained high yields of crops when treated and managed. In addition, the land must have been used for irrigated agricultural production in the last four years to qualify under this category.
- **Farmland of Statewide Importance**. Farmland of Statewide Importance is similar to Prime Farmland in that it has a good combination of physical and chemical characteristics for crop production, but with minor shortcomings, such as greater slopes and less ability to store moisture.
- **Unique Farmland**. This land does not meet the criteria for Prime Farmland or Farmland of Statewide Importance, but is land that has been used for the production of the State's leading agricultural crops. This land is usually irrigated, but may include non-irrigated orchards or vineyards, as found in some climatic zones of California. Unique Farmland must have been cropped at some time during the four years prior to the mapping date.

- **Farmland of Local Importance**. This category applies to land of importance to the local agricultural economy, as determined by the county. This land is either currently producing crops or has the capability of production, but does not meet the criteria of the preceding categories.
- **Grazing Land.** Grazing Land is land on which the vegetation is suited to the grazing of livestock.
- **Urban and Built-up Land**. This land is occupied by structures with a building density of at least one unit to 1.5 acres, or approximately six structures on a 10-acre parcel. This land generally provides unfavorable conditions for agricultural production.
- **Other Land**. This is land that is not included in any of the categories above and may include brush, timber, wetlands, confined livestock areas, strip mines, and gravel pits, among other land types.

Farmland Designations in the Project Area

All of the proposed Project facility sites are mapped as Urban and Built-up Land (CDC 2011). No farmland is mapped in the study area (CDC 2011).

Williamson Act Program

As described below in Section 5.19.2.2 (State Regulations), the California Land Conservation Act (commonly referred to as the Williamson Act) is the State's primary program for the conservation of private land for agricultural and open space uses. The CDC prepares countywide maps of lands enrolled in Williamson Act contracts and classifies them into the categories described below.

- **Prime Agricultural Land**. This category represents the State's highest quality agricultural land. Land under this category is typically used for the production of irrigated crops or to support livestock.

- **Non-prime Agricultural Land**. This category represents Open Space Land of Statewide Significance, as defined under the California Open Space Subvention Act. Most land under this category is in agricultural uses such as grazing or non-irrigated crops and may also include other open space uses that are compatible with agriculture and consistent with local general plans.

- **Land in Non-renewal**. This category represents land under contracts that are being terminated at the option of the landowner or local government.

Williamson Act Contracts in the Study Area

No lands in the study area are enrolled in the Williamson Act program (CDC 2007).

5.19.1.2 Forest Resources

Section 12220(g) of the California Public Resources Code defines forest land as "land that can support 10 percent native tree cover of any species, including hardwoods, under natural conditions, and that allows for management of one or more forest resources, including timber, aesthetics, fish and wildlife, biodiversity, water quality, recreation and other public benefits." Timberland is land that is available for and capable of growing a crop of trees of any commercial species used to produce lumber and other forest products (Public Resources Code Section 4526). Under this definition, timberland does not include land owned by the federal government and land designated by the California Board of Forestry and Fire Protection as experimental forest land. There is no forest land within the study area.

5.19.2 Regulatory Framework

5.19.2.1 Federal Regulations

The Farmland Protection and Policy Act (FPPA) requires an evaluation of the relative value of farmland that could be affected by decisions sponsored in whole or part by the federal government. The FPPA is intended to minimize the impact federal programs have on the unnecessary and irreversible conversion of farmland to nonagricultural uses. It assures that, to the extent possible, federal programs are administered to be compatible with State, local units of government, and private programs and policies to protect farmland (USDA 2011). For the purpose of FPPA, farmland includes prime farmland, unique farmland, and land of statewide or local importance. Farmland subject to FPPA requirements includes forest land, pastureland, cropland, or other land, but not water or urban built-up land. The FPPA does not apply to the proposed Project, because lands in the study area are mapped as Built-up Lands.

5.19.2.2 State Regulations

As noted in Section 5.19.1.1 (Agricultural Resources), the California Land Conservation Act of 1965, commonly referred to as the Williamson Act, is the State's primary program aimed at conserving private land for agricultural and open space use. It is a voluntary, locally-administered program that offers reduced property taxes on lands whose owners place enforceable restrictions on land use through contracts between the individual landowners and local governments. As also indicated in Section 5.19.1.1 (Agricultural Resources), there are no lands in the study area that are enrolled in the Williamson Act program. Therefore, land use restrictions imposed by the Williamson Act are not applicable to the proposed Project.

5.19.2.3 Local Regulations

Local planning agencies regulate land uses, including agricultural uses, through general plan policies and zoning designations, which specify allowable uses within their jurisdictions. The San Francisco Public Utilities Commission (SFPUC) is not subject to local land use policies and zoning ordinances (refer to Chapter 4, Plans and Policies), although it seeks to work cooperatively with local jurisdictions to avoid conflicts. However, none of the facility sites would be located on land designated by a local general plan or zoned for agriculture or forestry (Colma 2009, 2010; Daly City 1987, 2003; Millbrae 1998, 2012; San Bruno 2007, 2009; San Mateo County 1986a, 1986b, 1999, n.d.; South San Francisco 1999, 2010).

5.19.3 Impacts and Mitigation Measures

5.19.3.1 Significance Criteria

For the purposes of this EIR, the Regional Groundwater Storage and Recovery Project would have a significant effect on agriculture and forest resources if it were to:

- Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance, as shown on maps prepared pursuant to the Farmland Mapping and Monitoring Program of the California Natural Resources Agency, to non-agricultural use.
- Conflict with existing zoning for agricultural use or a Williamson Act contract.
- Conflict with existing zoning for, or cause rezoning of, forest land (as defined in Public Resources Code Section 12220[g]) or timberland (as defined by Public Resources Code Section 4526).
- Result in the loss of forest land or the conversion of forest land to non-forest use.
- Involve other changes in the existing environment, which, due to their location or nature, could result in the conversion of farmland to non-agricultural use or forest land to non-forest use.

5.19.3.2 Approach to Analysis

Due to the location of the Project, no impacts would occur related to the five impact criteria listed above; therefore, no impact discussion is provided for these topics for the reasons presented below:

Convert mapped farmland to non-agricultural use. The proposed Project's facility sites are not located on or in the vicinity of land mapped as farmland. Therefore, the first significance criterion listed above is not applicable to the Project and is not discussed further.

Conflict with zoning for agricultural use or with a Williamson Act contract. The proposed Project's facility sites are not located on land zoned for agricultural uses or subject to a Williamson Act contract. Therefore, the second significance criterion listed above is not applicable to the Project and is not discussed further.

Conflict with existing zoning for, or cause rezoning of, forest land, or result in the loss of forest land or the conversion of forest land to non-forest use. No land in the study area is either zoned for forestry or meets the definition of forest land. Thus, neither construction nor operation of the proposed Project would conflict with zoning regulations for forest land, result in the loss of forest land, or result in the conversion of forest land to non-forest use. Therefore, the third and fourth significance criteria listed above are not applicable to the proposed Project and are not discussed further.

Involve other changes in the existing environment, which, due to their location or nature, could result in the conversion of farmland to non-agricultural use or forest land to non-forest use. The facility sites would be located on land designated as Urban and Built-up Land. The proposed Project would install and operate improvements (well facilities and an upgrade at the Westlake Pump Station) for water supply and, therefore, would not involve changes that would result in conversion of farmland to non-agricultural use or forest land to non-forest use. Thus, the fifth criterion listed above is not applicable to the proposed Project and is not discussed further.

5.19.3.3 Construction and Operational Impacts and Mitigation Measures

As discussed above, the Project would not cause impacts to agriculture or forest resources. Therefore, no mitigation measures related to this resource topic are required.

5.19.3.4 Cumulative Impacts and Mitigation Measures

Because the GSR Project would not result in Project-specific impacts related to agriculture or forest resources, implementation of the Project would not result in cumulative impacts to these resources.

6.1 GROWTH INDUCEMENT

6.1.1 Introduction and Overview

This chapter analyzes the growth inducement potential and associated secondary effects of growth impacts of the proposed Project, as required by the California Environmental Quality Act (CEQA). CEQA requires that an Environmental Impact Report (EIR) evaluate the growth inducing impacts of a proposed Project. A growth-inducing impact is defined as follows:

> "[T]he ways in which the proposed project could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment. Included in this are projects which would remove obstacles to population growth… It must not be assumed that growth in any area is necessarily beneficial, detrimental, or of little significance to the environment" (CEQA Guidelines Section 15126.2[d]).

As described in Chapter 2 Introduction and Background, Section 2.2 (Project Background), the San Francisco Planning Department prepared a Program Environmental Impact Report (PEIR) on the San Francisco Public Utilities Commission's (SFPUC) Water System Improvement Program (WSIP), which was certified in October 2008 (San Francisco Planning Department 2008). The PEIR includes a detailed analysis of the growth inducement potential of the overall WSIP water supply strategy and concluded that "The WSIP would support planned growth in the existing SFPUC service area (WSIP PEIR, Volume. 4, Chapter 7, Impact 7-1)."

The proposed GSR Project, as a dry-year supply project of the WSIP, would be a contributing factor in that growth inducement potential and associated indirect effects of growth. By removing the lack of a reliable water supply and supply system as one potential obstacle to growth within the SFPUC service area, the WSIP, and thus the proposed Project, would have an indirect growth-inducing effect according to the CEQA definition above[1]. This EIR tiers from the WSIP PEIR, and the growth inducement analysis contained in PEIR Chapter 7 and PEIR Appendix E are incorporated by reference into this EIR. All impacts related to the WSIP water supply strategy to which the Project contributes have been examined at a sufficient level of detail in the PEIR and no additional review is necessary in this EIR. The significant environmental effects have been adequately addressed in the PEIR and the SFPUC has adopted the CEQA Findings on the PEIR related to the growth inducing impacts of the WSIP. A summary of the growth inducement analysis in the PEIR is provided below.

6.1.2 Summary of PEIR Growth Inducement Analysis

Implementation of the WSIP would achieve the WSIP goals and objectives, including the water supply goal through the year 2018. It would allow the SFPUC to: (1) meet its customer water needs in non-drought periods through the year 2018 and (2) limit rationing to a maximum of 20 percent reduction in water service system-wide during extended droughts. Achieving the WSIP water supply goal would increase the reliability of water service to existing customers and provide water to serve planned growth of additional residential and business customers in the existing SFPUC service area.

A variety of factors influence new development or population growth in the area served by the SFPUC's water, including economic conditions of the region, adopted growth management policies in the affected communities and the availability of adequate infrastructure (e.g., water service, sewer service, public schools and roadways), with economic factors generally the leading driver. While water service is only one of many factors affecting the growth potential of a community, it is one of the chief public services needed to support urban development, and lack of a reliable water supply as well as a service capacity deficiency could constrain future development.

Pursuant to CEQA, growth per se is not assumed to be necessarily beneficial, detrimental, or of little significance to the environment; it is the secondary, or indirect, effects of growth that can cause adverse changes to the physical environment. The indirect effects of population and/or economic growth and accompanying development can include increased demand on community services and public service infrastructure; increased traffic and noise; degradation of air and water quality; and conversion of agricultural land and open space to urban uses. Local land use plans (e.g., general plans and specific plans) of the jurisdictions served by the SFPUC establish land use development patterns and growth policies that are intended to allow for the orderly expansion of urban development supported by adequate public services, including water supply, roadway infrastructure, sewer service and solid waste service. Local jurisdictions conduct CEQA environmental review on their general and specific plans to assess the secondary effects of their planned growth and to identify feasible mitigation for significant, adverse effects. A project that would induce growth and is inconsistent with local land use plans and policies could indirectly cause adverse environmental impacts, as well as impacts on public services; this

---

[1] The WSIP would not *directly* induce growth as it does not involve the development of new housing to attract additional population, nor would it indirectly induce growth by establishing substantial permanent or even short term construction employment opportunities that could stimulate population growth. Construction of the WSIP projects is not expected to involve employment opportunities substantially beyond what would normally be available to construction workers in the area, and workers are expected to be drawn from the local labor pool.

could occur if the local land use jurisdictions have not previously addressed these issues in the CEQA review of their land use plans and development proposals.

By removing the lack of a reliable water supply and water system (as one potential obstacle to growth within the SFPUC service area), providing and assisting in the development of additional water supply sources (such as recycled water and groundwater projects) and promoting of more efficient use of water through conservation measures, the WSIP would have an indirect growth-inducing effect according to the CEQA definition. The WSIP would support growth in the SFPUC service area through 2018; although it appears that some growth would occur irrespective of the WSIP due to increased water delivery efficiencies (e.g., plumbing code changes), conservation and other water supply sources. Growth would in turn result in indirect effects. In most cases, the effects of population and employment growth have been identified and addressed in the EIRs for the general plans and associated area plans and specific plans adopted by the jurisdictions in the service area. Some of the identified indirect effects of growth are significant and unavoidable; others are significant, but can be mitigated.

Potentially significant and unavoidable impacts as a result of growth in the SFPUC service area have been identified by the local jurisdictions in the following areas: traffic congestion, air pollution, traffic noise, construction noise, increased demand for public schools and other public services, loss of recreational opportunities and impacts on visual quality resulting from the loss of open space, cumulative effects on over-utilized parks, loss of wildlife habitat and wetlands and impacts on other biological resources, cumulative impacts on cultural resources, increased flooding potential, increased urban runoff pollutants, seismic hazards, induced population growth, failure to meet housing demand for projected population growth, exposure of new development to contaminated soil or groundwater, insufficient water supply, insufficient wastewater disposal capacity, loss of agricultural resources, land use conflicts, conflicts with existing land use plans or policies, and changes in density, scale and character of an area.

The adopted WSIP would have growth-inducement potential through 2018 because the SFPUC (with the cooperation of the wholesale customers) would provide the additional water supply to meet purchase requests through 2018. The WSIP would support much of the growth through 2018 in the jurisdictions served by the regional water system. In general, development that was planned and approved through the general plan process in the SFPUC service area would have environmental impacts. The environmental consequences of this planned growth have been largely addressed in local plans and the associated CEQA review, as well as in other, project-specific documentation. In a number of jurisdictions, negative declarations or mitigated negative declarations were prepared for general plans and related planning documents that were found not to have significant environmental effects.

The PEIR does not identify any mitigation measures for implementation by the SFPUC that could substantially decrease or eliminate growth-inducing impacts. This is because the SFPUC does not have control over the decisions that each local agency will make with respect to growth in their jurisdictions. Individual agencies' general plans and environmental documents contain actions, limitations and mitigation measures that will be implemented in the individual jurisdictions with local development project or program approvals. These types of mitigation measures were identified in the PEIR (see PEIR Chapter 7 and PEIR Appendix E, which are incorporated by reference into this EIR) (San Francisco Planning Department 2008).

To assess the growth inducement potential of the WSIP and characterize the secondary effects of growth, the PEIR investigates the following questions:

- What assumptions did the SFPUC and its wholesale customers make regarding growth (population and employment) in projecting future (2030) total water demand and customer purchases from the SFPUC?
- Are these assumptions consistent with forecasts prepared and used by local and regional planning agencies (e.g., Association of Bay Area Governments [ABAG], counties, and cities) within the service area? What are the growth trends in the Bay Area region?
- Are there any notable inconsistencies between the population and employment forecasts used by the SFPUC and the wholesale customers, and those of the local and regional planning agencies that suggest that the water supply planning efforts are inconsistent with land use planning efforts?
- Is the level of growth projected for 2030 consistent with that identified and planned for in existing adopted general plans?
- What are the potential environmental impacts (i.e., secondary effects) associated with growth projected to occur in the service area? Have these impacts been evaluated in previous CEQA review documents on existing general and specific plans?
- What mitigation measures and findings have the local jurisdictions adopted as part of approving their future growth plans?

  The issues raised in these questions are summarized below and addressed in detail in PEIR Chapter 7 (Volume 4) and supplemented by PEIR Appendix E (Volume 5).

- **SFPUC Projections (PEIR Section 7.2).** Accurate demand projections are important in ensuring that future water supplies will be adequate while not surpassing the needs of planned growth. The SFPUC and its customers used computer models to forecast future water demand. PEIR Section 7.2 presents an overview of the SFPUC water service area and describes key factors (assumptions, inputs and methodologies) used in estimating future demand that relate to growth and inform comparisons between water demand and land use planning projections. These factors include baseline population, methodology used to determine existing water usage by land use/account type, the current water supply agreement between the SFPUC and its wholesale customers, and assumptions regarding future land use patterns, water conservation and recycling, and water from other (non-SFPUC) sources through 2030. The demand estimates, in conjunction with estimates of savings from conservation and use of other water sources, provide the basis for the 2030 purchase estimates.
- **Growth Inducement Potential (PEIR Section 7.3).** This section analyzes the WSIP's growth inducement potential: whether the demand to be met by the WSIP would be consistent with local plans and policies or could contribute to growth in the service area beyond that called for in the existing general plan. To gauge the consistency of the WSIP with growth planned in the jurisdictions served by the SFPUC, the analysis compares the growth assumed in the SFPUC projections with growth forecasts (a) developed by ABAG and (b) reflected in

adopted land use plans in the service area. With respect to ABAG, this section also describes ABAG's changing expectations about growth as reflected in its updated projections issued in 2002, 2003, and 2005.

- **Indirect Effects of Growth (PEIR Section 7.4).** Growth (whether planned or unplanned) can cause environmental impacts. Section 7.4 of the PEIR describes the potential impacts of growth that could be supported, in part, by implementation of the WSIP. This section also identifies measures adopted to reduce, eliminate or otherwise mitigate the impacts of planned growth.

6.1.3 Summary of Conclusions

A review of historical growth trends of a selection of jurisdictions in the service area, based primarily on information in general plans and Bay Area Water Supply and Conservation Association profiles, shows that:

- Cities in the service area are largely urbanized, most having experienced their most rapid growth in the postwar decades through the 1970s.
- Milpitas and East Palo Alto have experienced high rates of growth more recently.
- San Francisco's population fluctuated somewhat, but on average has been essentially stable over the past 50 years.
- Many jurisdictions cannot grow laterally and their general plans include policies to manage growth. Many general plans identify strategies consistent with "smart growth" principles, such as encouraging infill development and the redevelopment of previously developed areas, as means to accommodate future growth.
- The SFPUC's wholesale customers vary widely, in a variety of ways: by size; overall demand projected for 2030; the change that the 2030 demand represents in absolute terms and as a percentage of 2001 demand; and the degree to which the customers depend on the SFPUC for their water supply. As such, the WSIP would remove growth obstacles to varying degrees within the service area.

As stated above, the complete growth inducement analysis is included in PEIR Chapter 7 and PEIR Appendix E, which are incorporated into this EIR by reference.

6.1.4 Indirect Effects of Growth

The indirect effects of growth expected in the general plans of jurisdictions in the service area have been identified in the EIRs prepared for those plans. Impacts commonly identified as significant and unavoidable and those commonly identified as significant, but mitigable, are presented in PEIR Section 7.4 and summarized briefly.

- The most commonly identified significant and unavoidable impacts of growth are:
  - Increased traffic congestion,
  - Deterioration of air quality, and
  - Cumulative effects of increased air pollutant emissions and noise.
- Mitigation measures have been adopted by local jurisdictions as part of their general plan approval processes to address the secondary effects of planned growth. These measures are summarized in PEIR Appendix E.
- Two cities, Foster City and City of San Mateo, identified increased demand for potable water supply as a significant and unavoidable effect of growth; the WSIP would address this issue in those two cities.
- Overriding considerations commonly adopted by the decision-making bodies in adopting their general plans include the following:
  - Accommodation of growth in an orderly, fiscally sound manner
  - Economic diversification and job generation
  - Creation of housing, furtherance of regional housing share objectives, and provision of affordable housing
  - Improvements of the local jobs/housing balance
  - Increased sales revenue and positive fiscal impact
  - Promotion of alternative modes of travel to reduce reliance on private vehicles
  - Establishment of policies to preserve natural areas and open space lands
- For many cities that receive water from the regional water system, the supply to be provided under the WSIP supports and is consistent with the planned growth reflected in their existing adopted general plans. For other communities, it appears that the WSIP supply (in combination with other supply sources available to those communities), could serve a level of growth beyond that identified in the existing general plans. In those cases, secondary effects of such growth could include impacts related to increased density and impacts related to development of new land areas.
  - Density related impacts could include increased traffic congestion, air pollution, traffic noise, construction noise and demand on public services.
  - Land area related impacts could include loss of open space and agricultural land, as well as loss of and degradation of water quality due to increases in impervious surface area.

The proposed GSR Project would not directly induce population or economic growth, nor would it tax existing community service facilities or encourage other activities that could significantly affect the environment. However, as described above, the GSR Project is one of the groundwater projects that comprise the WSIP and, therefore, its implementation would contribute to the growth inducement potential of the WSIP and the associated indirect effects of growth. Implementation of the GSR Project would thus contribute to an incremental portion of the growth inducement impacts and associated indirect impacts of growth of the WSIP. See Chapter 7 of the PEIR for a detailed analysis of the WSIP's growth inducement effects (San Francisco Planning Department 2008).

6.2 SUMMARY OF CUMULATIVE IMPACTS

As described in Chapter 5 Environmental Setting, Impacts, and Mitigation Measures, Section 5.1.7 (Cumulative Impacts), cumulative impacts are defined as "two or more individual effects which, when considered together, are considerable or which compound or increase other environmental impacts" (CEQA Guidelines Section 15355). Cumulative impacts can result from individually minor, but collectively significant actions when added to those of other closely related past, present or reasonably foreseeable future projects. The cumulative impacts from several projects are the change in the environment that results from the incremental impact of the project when added to other closely related past, present and reasonably foreseeable future projects. The cumulative analysis in this EIR identifies Project impacts that would be individually limited, but when viewed in connection with the effects of other past, present and reasonably foreseeable future projects, could be "cumulatively considerable" with regard to the Project's contribution to a cumulative impact.

In Chapter 5 Environmental Setting, Impacts, and Mitigation Measures, cumulative impacts are discussed and analyzed under each resource area immediately following the description of the direct impacts of the proposed Project and the identified mitigation measures for that resource area. The analyses of cumulative impacts are based on the same setting, regulatory framework and significance criteria as the direct impacts, and it applies the results of the project-level, direct impact analysis within the context of the identified geographic scope of the area affected by the cumulative effect. Table 5.1-3 (Projects Considered for Cumulative Impacts) lists the relevant past, present and reasonably foreseeable future projects proposed by the SFPUC and other jurisdictions that are considered in the cumulative impact analysis. Figure 5.1-3 (Location of Projects Considered in the Cumulative Analysis), shows the location of the cumulative projects.

Table 6-1 (Summary of Significant Cumulative Impacts), provides a summary of the cumulative impacts associated with the GSR Project that are significant. All significant cumulative impacts could be reduced to less-than-significant levels with implementation of mitigation measures identified in Chapter 5, Environmental Setting, Impacts, and Mitigation Measures, except for unavoidable noise, and well interference impacts. See Chapter 5 for a detailed discussion of cumulative impacts by resource topic, and where appropriate, a description of mitigation measures that would avoid or lessen the cumulative impacts.

TABLE 6-1
Summary of Significant Cumulative Impacts

Impact	Significance Determination
Impact C-LU-1. Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to land use.	SUM
Impact C-AE-1: Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to scenic resources and visual character.	LSM
Impact C-CR-1: Construction of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts on historical, archaeological, or paleontological resources, or human remains.	LSM
Impact C-TR-1: Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to transportation and circulation.	LSM
Impact C-NO-1: Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to noise.	SUM
Impact C-AQ-1: Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to air quality.	LSM
Impact C-UT-1: Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to utilities and service systems.	LSM
Impact C-BR-1: Construction and operation of the proposed Project could result in significant cumulative impacts related to biological resources.	LSM
Impact C-BR-2: The Project would result in cumulative construction or operational impacts related to special-status species, riparian habitat, sensitive communities, wetlands, or waters of the United States, or compliance with local policies and ordinances protecting biological resources at Lake Merced.	LSM
Impact C-HY-1: Project construction could result in a cumulatively considerable contribution to cumulative impacts on hydrology and water quality.	LSM
Impact C-HY-2: Operation of the proposed Project would result in a cumulative considerable contribution to cumulative impacts related to well interference.	SUM
Impact C-HY-5: The proposed Project, in combination with past, present, and reasonably foreseeable future projects, could have a substantial adverse effect on water quality that could affect the beneficial uses of surface waters.	LSM
Impact C-HY-8: Operation of the proposed Project would have a cumulatively considerable contribution to a cumulative impact related to groundwater depletion effect.	LSM
Impact C-HZ-1: Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to hazards and hazardous materials.	LSM

Notes:

LSM = Less than Significant with Mitigation

SUM = Significant and Unavoidable with Mitigation

6.3 SIGNIFICANT ENVIRONMENTAL EFFECTS THAT CANNOT BE AVOIDED IF THE PROPOSED PROJECT IS IMPLEMENTED

In accordance with Section 21100(b)(2)(A) of CEQA and with Sections 15126(b) and 15126.2(b) of the CEQA Guidelines, the purpose of this section is to identify project-related environmental impacts that could not be eliminated or reduced to a less-than-significant level with implementation of mitigation measures identified in Chapter 5 Environmental Setting, Impacts, and Mitigation Measures. The findings in this chapter are subject to final determination by the San Francisco Planning Commission as part of its certification of the EIR.

6.3.1 Significant and Unavoidable Effects of the Proposed Project

This section identifies Project impacts that, even with the implementation of all identified mitigation measures, would remain significant and are, therefore, considered *unavoidable*. All GSR Project impacts would either be less than significant or reduced to less-than-significant levels with implementation of the identified mitigation measures except for unavoidable land use, aesthetics, well interference, and noise impacts. The analysis presented in Chapter 5 Environmental Setting, Impacts, and Mitigation Measures, of this EIR concludes that implementation of the proposed Project would result in four significant and unavoidable impacts:

- Project construction would result in significant and unavoidable impacts associated with construction noise and the temporary increase in ambient noise levels and exceedance of local noise standards. Even with implementation of all feasible noise-reducing mitigation measures, a significant impact would remain with mitigation at Sites 1, 3, 4, 5 (On-site Treatment), 9, 12, 14, 16, 18 (Alternate), and 19 (Alternate) (see Section 5.7, Noise and Vibration, Impacts NO-1, NO-3, and C-NO-1).
- Similarly, Project construction would have a substantial temporary impact on the existing character of the area surrounding well facility sites and could substantially disrupt existing land uses near Sites 1, 3, 4, 5, (On-site Treatment), 9, 12, 14, 16, 18 (Alternate), and 19 (Alternate). These impacts would remain significant and unavoidable after implementation of mitigation measures (see Section 5.2, Land Use, Impacts LU-1 and C-LU-1).
- Project construction would result in a significant and unavoidable impact on the visual character of the area surrounding Site 7, related to the removal of trees. Even with implementation of all feasible mitigation measures, the significant impact would remain at Site 7 (see Section 5.3, Aesthetics, Impact AE-1).
- Operation of the project would decrease the production rate of existing wells due to localized groundwater drawdown within the Westside Groundwater Basin such that existing or planned land uses may not be fully supported. Mitigation could reduce impacts to less than significant. However, feasibility of mitigation would vary depending on the willingness of the well owner to allow the SFPUC to implement mitigation, which would have to take place on the property of existing irrigators. Because such assurance has not yet been provided, the

impact is considered significant and potentially unavoidable (see Section 5.16, Hydrology and Water Quality, Impacts HY-7 and C-HY-2).

6.3.2 Significant and Unavoidable Effects of the WSIP

The proposed Project is one of the groundwater projects that comprise the SFPUC's WSIP. Insofar as the proposed Project is a component of the WSIP, it would contribute to the WSIP's significant and unavoidable, and potentially significant and unavoidable water supply and growth-inducement impacts, as identified in the WSIP PEIR (San Francisco Planning Department 2008) and summarized below:

- By providing water to support planned growth in the SFPUC service area, the WSIP will result in significant and unavoidable growth inducement effects that are primarily related to secondary effects such as air quality, traffic congestion and water quality. These impacts were adequately addressed in the PEIR at a sufficient level of detail such that no further analysis is required in this EIR. The analysis contained in the PEIR is incorporated into this EIR by this reference (see PEIR Chapter 7).
- Based on the best available information at that time, the PEIR made the conservative determination that the WSIP could result in a significant and unavoidable impact on fishery resources in Crystal Springs Reservoir related to inundation of spawning habitat upstream of the reservoir (see PEIR Chapter 5, Section 5.5.5, Impact 5.5.5-1). The project-level fisheries analysis in the Lower Crystal Springs Dam Improvements Project EIR modifies certain PEIR impact determinations based upon more detailed site-specific data and analysis. These project-level conclusions supersede any contrary impact conclusions in the PEIR. Project-level review of updated, site-specific information that was developed following certification of the PEIR was incorporated into the project-level EIR for the Lower Crystal Springs Dam Improvements Project, and the project-level analysis determined that impacts on fishery resources due to inundation effects would be less than significant (San Francisco Planning Department 2010).
- Based on the best available information at that time, the PEIR made the conservative determination that the WSIP would result in a significant and unavoidable impact related to flow along Alameda Creek below the Alameda Creek Diversion Dam ("Alameda Creek Hydrologic Impact") (see PEIR Chapter 4, Section 5.4.1, Impact 5.4.1-2). The project-level analysis in the Calaveras Dam Replacement Project EIR modifies this PEIR impact determination to be less than significant based upon more detailed site-specific data and analysis (San Francisco Planning Department 2011). These project-level conclusions supersede the contrary impact conclusions in the PEIR.

6.4 SIGNIFICANT IRREVERSIBLE ENVIRONMENTAL CHANGES

In accordance with CEQA Section 21100(b)(2)(B) and CEQA Guidelines Sections 15126(c) and 15126.2(c), the purpose of this section is to identify significant irreversible environmental changes that would be caused by the proposed Project. Construction activities associated with the GSR Project would result in an irretrievable and irreversible commitment of natural resources through the use of power supply and construction materials. In addition, the construction of new facilities (e.g., new wells and water treatment facilities) would result in an irretrievable or irreversible commitment of land to water supply uses. However, these uses would take up limited land area and are compatible with adjacent land uses.

The proposed GSR Project would require the commitment of energy resources to fuel and maintain construction equipment (such as gasoline, diesel and oil) during the construction period. Project construction would commit resources, such as concrete and steel, to be used for the proposed facilities and related improvements.

7.1 INTRODUCTION

This chapter presents the California Environmental Quality Act (CEQA) alternatives analysis for the Groundwater Storage and Recovery Project (GSR Project or Project). The CEQA Guidelines, Section 15126.6(a), state that an Environmental Impact Report (EIR) must describe and evaluate a reasonable range of alternatives to a project that would feasibly attain most of the project's basic objectives, but that would avoid or substantially lessen any identified significant adverse environmental effects of the project. Specifically, the CEQA Guidelines (Section 15126.6) set forth the following criteria for selecting and evaluating alternatives:

- **Identifying Alternatives**. The selection of alternatives is limited to those that would avoid or substantially lessen any of the significant effects of the project, are feasible, and would attain most of the basic objectives of the project. Among the factors that may be considered when addressing the feasibility of an alternative are site suitability, availability of infrastructure, general plan consistency, other plans or regulatory limitations, jurisdictional boundaries, economic viability, and whether the proponent can reasonably acquire, control, or otherwise have access to an alternative site. An EIR need not consider an alternative whose impact cannot be reasonably ascertained and whose implementation is remote and speculative. The specific alternative of "no project" must also be evaluated.
- **Range of Alternatives**. An EIR need not consider every conceivable alternative, but must consider and discuss a reasonable range of feasible alternatives in a manner that will foster informed decision-making and public participation. The "rule of reason" governs the selection and consideration of EIR alternatives, requiring that an EIR set forth only those alternatives necessary to permit a reasoned choice. The lead agency (the City and County of San Francisco [CCSF]) is responsible for selecting a range of project alternatives to be examined and for disclosing its reasons for the selection of the alternatives.

- **Evaluation of Alternatives**. EIRs are required to include sufficient information about each alternative to allow meaningful evaluation, analysis, and comparison with the proposed project. Matrices may be used to display the major characteristics and the environmental effects of each alternative. If an alternative would cause one or more significant effects that would not result from the project as proposed, the significant effects of the alternative must be discussed, but in less detail than the significant effects of the project.

This chapter is organized in the following sections, following this introductory section:

Section 7.2, WSIP Alternatives, summarizes the seven alternatives to the San Francisco Public Utilities Commission (SFPUC) Water System Improvement Program (WSIP) that were evaluated in the WSIP Program EIR (PEIR). As required by CEQA, the PEIR evaluated a range of alternatives to the WSIP. The GSR Project is the primary drought supply project under the WSIP.

Section 7.3, GSR Alternatives Analysis, describes the alternatives selection process and the objectives of the Project; summarizes the significant impacts of the Project; describes the alternatives selected for detailed analysis; and compares the environmental impacts of each alternative to those of the proposed Project.

Section 7.4, Comparison of Alternatives, provides a summary comparison of the alternatives, including the No Project Alternative, to the proposed Project. It includes a summary of environmental impacts, a discussion regarding the ability of each alternative to meet project objectives.

Section 7.5, Environmentally Superior Alternative, identifies the environmentally superior alternative.

Section 7.6, Alternatives Considered but Rejected from Further Consideration, includes a description of the alternatives that were considered for evaluation in this Draft EIR and the reasons they were rejected from further consideration. Alternatives were eliminated from detailed consideration in this Draft EIR where they failed to meet most of the basic project objectives, were infeasible, and/or would not avoid any significant environmental effects.

7.2 WSIP ALTERNATIVES

As discussed in Chapter 2, Introduction and Background, the SFPUC approved implementation of the Phased WSIP in October 2008. The WSIP is a comprehensive program to improve the reliability of the regional water system with respect to water quality, seismic response, and water delivery based on a planning horizon through the year 2030, as well as to improve the system with respect to water supply to meet water delivery needs in the service area through the year 2018. To the extent that the GSR Project would contribute to achieving the goals and objectives of the WSIP, the analysis of the WSIP alternatives applies to the alternatives analysis of the GSR Project.

The San Francisco Planning Department, Environmental Planning Division (EP) considered systemwide alternatives to the WSIP in the PEIR, which the San Francisco Planning Commission certified on October 30, 2008. The PEIR evaluated seven alternatives to the WSIP because of their apparent ability to meet most of the WSIP's goals, their ability to reduce one or more of the significant impacts associated with program implementation, their potential feasibility, and their collective ability to provide a reasonable range of alternatives to foster informed decision-making and public participation. Analysis of the No Program Alternative was included in the PEIR as required by CEQA.

The San Francisco Planning Commission certified the PEIR in October 2008 (Planning Commission Motion No. 17734). Thereafter, the SFPUC approved the Phased WSIP and adopted the CEQA Findings on the WSIP (SFPUC Resolution 08-0200). The Phased WSIP incorporates elements of three alternatives analyzed in the PEIR: the No Purchase Request Increase Alternative, the Aggressive Conservation/Water Recycling and Groundwater Alternative, and the Modified WSIP Alternative. Chapters 9 and 14 of the PEIR include more detailed descriptions of these WSIP alternatives and also present the associated program-level environmental analysis of these alternatives. Chapter 13 of the PEIR includes additional information about the adopted Phased WSIP. All three of these chapters are incorporated into this EIR by reference. For informational purposes, the WSIP and the alternatives examined in the PEIR are summarized below.

- **WSIP Proposed Program**. The proposed program described and analyzed in the PEIR would establish program goals and system performance objectives in the areas of water quality, seismic reliability, delivery reliability, and water supply. The WSIP would provide for water supplies to serve customer purchase requests during non-drought and drought periods through 2030, including increased average annual diversions from the Tuolumne River, and would implement all key regional facility improvement projects.
- **No Program Alternative**. Under the No Program Alternative, the SFPUC would implement only those facility improvement projects driven by regulatory requirements or existing agreements with regulatory agencies. It would meet only the water quality goals of the WSIP and would fail to meet the other goals and objectives. It would endeavor to meet increasing customer purchase requests through the year 2030 by diverting additional Tuolumne River water only when available under the CCSF's existing water rights.
- **No Purchase Request Increase Alternative**. The No Purchase Request Increase Alternative is designed to serve the wholesale customers the amount of water required under the Master Water Sales Agreement between the CCSF and each of the wholesale customers in effect in 2008. It would thereby limit the ability of the system to meet customer purchase requests through 2030, but would include implementation of all key regional facility improvement projects.
- **Aggressive Conservation/Water Recycling and Local Groundwater Alternative**. Under the Aggressive Conservation/Water Recycling and Local Groundwater Alternative, the SFPUC would implement all of the key regional facility improvement projects, but would endeavor to serve the projected increase in customer purchase requests through 2030 only through additional conservation, water recycling, and local groundwater projects.
- **Lower Tuolumne River Diversion Alternative**. Under the Lower Tuolumne River Diversion Alternative, the SFPUC would implement all of the key regional facility improvement projects and would serve the projected increase in customer purchase requests through 2030 through diversions from the lower Tuolumne River near its confluence with the San Joaquin

River. This alternative would include construction and operation of additional conveyance and treatment facilities to divert, transport, treat, and blend the new supply into the regional water system.

- **Year-round Desalination at Oceanside Alternative**. Under the Year-round Desalination at Oceanside Alternative, the SFPUC would implement all of the key regional facility improvement projects and would construct a 25-million-gallons-per-day (mgd) desalination plant in San Francisco to serve the projected increase in customer purchase requests through 2030.
- **Regional Desalination for Drought Alternative**. Under the Regional Desalination for Drought Alternative, the SFPUC would implement all of the key regional facility improvement projects and would partner with other San Francisco Bay Area (Bay Area) water agencies to construct and operate a regional desalination plant that would provide the SFPUC with supplemental supply during drought years.
- **Modified WSIP Alternative**. Under the Modified WSIP Alternative, the SFPUC would implement all of the key regional facility improvement projects, but would modify proposed system operations to minimize environmental effects. This alternative would include the implementation of key mitigation measures identified in the PEIR.

The alternatives analysis in the PEIR identified the Modified WSIP Alternative as the environmentally superior alternative. As described above, the Phased WSIP was ultimately adopted by the SFPUC, which incorporates elements of the No Purchase Request Alternative, the Aggressive Conservation/Water Recycling and Groundwater Alternative, and the Modified WSIP Alternative.

7.3 GSR ALTERNATIVES ANALYSIS

7.3.1 Approach to Alternatives Selection

Consistent with CEQA, the approach to alternatives selection for this Project EIR focused on identifying alternatives that: (1) could meet most of the basic objectives of the GSR Project while reducing one or more of its significant impacts, (2) could foster informed decision-making and public participation, and (3) were feasible. The planning effort for the Project entailed consideration of multiple alternatives by the SFPUC and EP. Certain alternatives were eliminated from consideration based on their inability to meet most of the Project's basic objectives, their lack of feasibility, or their inability to reduce the Project's environmental impacts. Those alternatives retained for consideration are presented in Section 7.3.4 (Selected CEQA Alternatives). The alternatives eliminated and the reasons for their elimination are discussed in Section 7.5 (Environmentally Superior Alternative).

The proposed Project would increase the volume of groundwater in storage by allowing the South Westside Groundwater Basin to recharge naturally during normal and wet years. The increased volume of groundwater in storage would occur through a reduction in groundwater pumping by the Partner Agencies; this reduction in groundwater pumping would be made possible by increased surface water deliveries to the Partner Agencies from the regional water system in those years. This "conjunctive," or cooperative, use of the basin would allow recapture of the naturally stored water during dry years.

As discussed in Chapter 3, Section 3.2 (Project Goals and Objectives) the primary goal for the Project is to provide an additional dry-year water supply for the SFPUC and Partner Agencies. Specific objectives of the Project are to:

- Conjunctively manage the South Westside Groundwater Basin through the coordinated use of SFPUC surface water and groundwater pumped by the Partner Agencies;
- Provide supplemental SFPUC surface water to the Partner Agencies in normal and wet years, with a corresponding reduction of groundwater pumping by these agencies, which would then allow for in-lieu recharge of the South Westside Groundwater Basin;
- Increase the dry-year and emergency pumping capacity of the South Westside Groundwater Basin by 7.2 mgd; and
- Provide a new dry-year groundwater supply for SFPUC customers and increase water supply reliability during the 8.5-year design drought cycle[1].

These objectives support the goals and objectives of the SFPUC's WSIP (SFPUC Resolution No. 08-200). The Project is considered by the SFPUC to be a fundamental component of the WSIP; implementation of the proposed Project is one element of an overall program designed to achieve the established WSIP system performance objectives for delivery reliability and water quality.

7.3.2 Impacts of the Proposed Project

The proposed Project would have potentially significant impacts on land use, aesthetics, cultural and paleontological resources, transportation and circulation, noise, air quality, recreation, utilities and service systems, biological resources, geology and soils, hydrology and water quality, hazards and hazardous materials, and mineral and energy resources. These impacts are associated with construction and operation of the Project as discussed below:

Construction-related Impacts: With the exception of noise, land use, and aesthetics impacts during Project construction, all construction-related Project impacts were determined to have no impact (NI) or be less than significant (LS) or less than significant with mitigation (LSM). The Project's estimated construction-related noise levels at some of the sites were determined to result in significant impacts even with implementation of mitigation (SUM). Significant and unavoidable noise impacts would result from proposed nighttime well drilling that would conflict with local noise standards and/or exceed sleep interference thresholds and daytime construction that would exceed the speech interference thresholds at

[1] The SFPUC measures water supply reliability using an 8.5-year design drought for water supply planning purposes. The design drought is based on the hydrology of the six years of the worst historical drought (1987-1992) plus the 2.5 years of the 1976-1977 drought, for a combined total of an 8.5-year design drought sequence. For additional information on the design drought and its role in the environmental analysis in this EIR, refer to Section 3.2 in the Project Description.

the closest residential receptors (see Impacts NO-1 and NO-3 in Section 5.7, Noise and Vibration). Because of this temporary significant and unavoidable noise impact, temporary construction-related impacts on land use character were also considered to be significant and unavoidable (see Impact LU-1 in Section 5.2, Land Use).

Additionally, the Project would result in the removal of a portion of a locally-designated tree mass in the Town of Colma at Site 7 to accommodate construction of a well facility treatment building, and the impact was determined to be significant and unavoidable (for the preferred option of consolidated treatment at Site 6 and the on-site treatment option). Although a mitigation measure has been identified to potentially reduce the visual impacts associated with tree removal at this site, all trees in the construction area boundary may be removed due to construction safety concerns and trees may not be replanted in the SFPUC right-of-way in sufficient numbers and tree species following construction to reduce the aesthetic impacts to less than significant (see Impact AE-1 in Section 5.3, Aesthetics, Section 5.3.3.4 [Construction Impacts and Mitigation Measures]). All other construction-related significant impacts were determined to be *less than significant with mitigation* (LSM).

Operation-related Impacts: With the exception of hydrology and land use impacts during project operations, all operational-related impacts were determined to be less than significant or less than significant with mitigation. Potential impacts resulting from well interference during Project pumping were determined to be significant and potentially unavoidable because implementation of the identified mitigation would not be totally within the control of the SFPUC, and project operations could adversely impact existing irrigation wells in areas near GSR Project wells. Mitigation measures identified would effectively reduce impacts to existing irrigation wells to a less-than-significant level; however, since the successful implementation of the identified mitigation measure at all affected existing irrigation wells cannot be certain at this time (as it would depend on cooperation from existing irrigation well owners), the mitigation may not reduce all impacts to less-than-significant levels at all locations. Therefore, the potential impacts of well interference were determined to be significant and potentially unavoidable even with all feasible mitigation applied (see Impact HY-6 in Section 5.16, Hydrology and Water Quality). All other significant impacts related to Project operations were determined to be *less than significant with mitigation* (LSM).

All the impacts of the proposed Project, including the significance determination before and after mitigation, are listed in Table 1-1 (Summary of Impacts and Mitigation Measures) at the end of Chapter 1, Executive Summary, in Section 1.5 (Summary of Project Impacts and Mitigation Measures).

7.3.3 GSR Project Development and Site Screening

Prior to the start of the environmental review process, the SFPUC and the Partner Agencies (California Water Service Company [Cal Water], the City of Daly City, and the City of San Bruno) developed an Alternatives Analysis Report (AAR) to evaluate the potential to use the South Westside Groundwater

Basin[2] to store water in normal and wet years and develop in-lieu recharge of the Basin to increase the volume of water in storage that can be pumped in dry years (MWH 2007).

The AAR identifies and evaluates potential sites for the facilities needed to support the Project and achieve all the Project's goals and objectives. The AAR evaluated potential well and treatment facility sites based on evaluation criteria for identification of preferred facility locations.

The following is a list of evaluation criteria utilized in the AAR:

- **Well Site Suitability.** This evaluation included review of access to the site, the footprint of the site, underground obstructions, and horizontal setback distances.
- **Groundwater System Considerations.** This evaluation included review of potential well yield, groundwater quality, well interference, and geologic stability.
- **Distribution System Considerations.** This evaluation included proximity to existing Partner Agency and SFPUC conveyance and treatment facilities.
- **Land Use Considerations.** This evaluation included a review of land ownership, property acquisition, ease of permitting, and local acceptance.

Candidate well sites were identified, screened for suitability, displayed on maps, and evaluated with respect to the evaluation criteria. Preferred well sites were selected and analyzed using a hydraulic model of the water distribution system to evaluate whether the respective water systems would accommodate the estimated additional water at each proposed location.

The SFPUC developed the Project in conjunction with the Partner Agencies and other stakeholders with impact avoidance or reduction in mind. The SFPUC participated in a multi-agency collaborative effort to identify and rank new groundwater well locations; 48 potential well sites were identified and evaluated according to the criteria listed earlier in this section. The 48 potential well sites were reduced to 14 well sites through application of the evaluation criteria (MWH 2007). The SFPUC completed groundwater modeling for the 14 wells identified and found that the pumping rates needed to reach the desired 7.2 mgd could result in well interference and other potential well interference effects at the Partner Agency wells and among the 14 Project wells. As a result, the SFPUC increased the proposed number of wells to 16 wells to redistribute the required pumping over a larger geographic area and thereby reduce the potential for well interference. The SFPUC also has identified three alternate well sites to be implemented in the instance where up to three of the 16 preferred well facilities cannot be constructed due to infeasibility. Some well sites include alternate connections to the SFPUC or Partner Agency distribution systems. Also, the Project includes alternate treatment configurations for wells at Sites 5, 6, and 7; treatment may be located on site for each of these three, or consolidated for all three of these sites at Site 6 (MWH et al. 2008).

[2] The Westside Groundwater Basin has been administratively divided at the San Francisco-San Mateo County line.

7.3.4 Selected CEQA Alternatives

In accordance with CEQA requirements, an alternative must meet the following three criteria: 1) the alternative would attain most of a project's basic objectives; 2) the alternative would avoid or substantially reduce the significant environmental impacts of the proposed project; and 3) the alternative must be feasible. An EIR need not analyze an alternative whose impact cannot be reasonably ascertained and whose implementation is remote and speculative. Furthermore, an EIR need not consider every conceivable alternative, but must consider a reasonable range of alternatives that will foster well-informed decision-making and public participation.

This section describes the project alternatives that were selected and analyzed in accordance with CEQA Guidelines Section 15126.6(a). The five alternatives to the proposed Project selected for detailed analysis in this EIR are:

- **Alternative 1: No Project Alternative.** The SFPUC would not conjunctively manage the South Westside Groundwater Basin with the Partner Agencies and the basin would continue to be operated as it is now. The 16 wells and well facilities would not be constructed or operated, the Westlake Pump Station would not be upgraded, and a new drought water supply would not be developed. The six test wells installed at Sites 2 (Park Plaza Meter), 5 (Right-of-way at Serra Bowl), 6 (Right-of-way at Colma BART), 8 (Right-of-way at Serramonte Boulevard), 10 (Right-of-way at Hickey Boulevard), and 13 (South San Francisco Linear Park) would be abandoned in accordance with regulatory standards or converted to monitoring wells[3].
- **Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield.** This alternative would reduce impacts on Lake Merced associated with declining lake levels by reducing Project pumping near the lake by approximately 54 percent by eliminating construction and operation of Sites 1 (Lake Merced Golf Club) and 4 (Garden Village Elementary School)[4], but redistributing that pumping to wells located away from Lake Merced to maintain Project yield at 7.2 mgd. The Project has the potential to affect Lake Merced by both increasing lake levels during extended Put and Hold Periods and decreasing lake levels during and after a design drought. There is no alternative that can reduce the extent of both lake level increases and lake level declines. Declining lake levels cause a more extensive set of impacts, including impacts to water quality and wetlands, so this alternative was developed to address declining lake levels, as was Alternative 2B, which is described below.
- **Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield.** This alternative would reduce impacts on Lake Merced associated with declining lake levels by reducing Project pumping near the lake by approximately 54 percent (by eliminating construction and operation of Sites 1 and 4), thereby reducing Project yield from 7.2 mgd to approximately 6.2 mgd.

---

[3] Sites 2, 5, and 6 are located in Daly City. Site 8 is located in the Town of Colma and Sites 10 and 13 are located in South San Francisco.

[4] Site 1 is located in Daly City and Site 4 is located in Broadmoor, in unincorporated San Mateo County.

- **Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield.** This alternative would reduce impacts on existing irrigation wells in the Colma area by reducing Project pumping near Colma by approximately 32 percent (by eliminating construction and operation of Sites 7 [Right-of-way Colma Boulevard][5] and 8), but also by redistributing that pumping to wells located away from Colma to Daly City, unincorporated Broadmoor, and San Bruno, to maintain Project yield at 7.2 mgd. Alternative 3A represents an alternative that could be developed to decrease well interference for wells in a particular geographic area near proposed well facility sites while maintaining the overall project yield.
- **Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield.** This alternative would reduce impacts on existing irrigation wells in the Colma area by reducing Project pumping near Colma by approximately 32 percent (by eliminating construction and operation of Sites 7 and 8), thereby reducing Project yield from 7.2 mgd to approximately 6.0 mgd. Alternative 3B represents an alternative that could be developed to decrease well interference for wells in a particular geographic area near proposed well facility sites while reducing overall project yield.

Table 7-1 (Selected CEQA Alternatives) provides a brief description of these alternatives and highlights how they differ from the proposed Project. Sections 7.3.4.1 through 7.3.4.5, below, include an evaluation of the impacts of the five selected alternatives relative to those of the proposed Project. Because the alternatives are conceptual, the evaluation is based on the available information and reasonable assumptions about how each alternative would be implemented. Each project alternative presented below has been developed only for the Project's preferred 16 sites and does not include analysis of the proposed alternate sites; the proposed alternate sites are included in the Project Description and have been evaluated as part of the Project. For each project alternative, Sections 7.3.4.1 through 7.3.4.5 present the following:

- A description of the alternative, including the rationale for its selection. Each description discusses feasibility issues as well as assumptions regarding the construction methods likely to be used.
- An evaluation of the alternative's ability to meet project goals and objectives. Evaluation of hydrologic and water quality impacts of the alternatives is, in part, dependent upon the groundwater modeling undertaken for the evaluation of the Project. Refer to Chapter 5, Environmental Setting, Impacts, and Mitigation Measures, Section 5.1.6 (Groundwater Modeling Overview) for an explanation of the groundwater model and its assumptions and limitations.
- Analysis of the environmental impacts of each alternative compared to those of the proposed Project.

---

[5] Site 7 is located in Colma.

The significant impacts of the proposed Project and the alternatives are presented in Table 7-2 (Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project), which follows discussion of each of the alternatives in Section 7.4 (Comparison of Alternatives).

TABLE 7-1
Selected CEQA Alternatives

Alternative	How Does the Alternative Differ from the Proposed Project?
Alternative 1: No Project. The SFPUC would not conjunctively manage the South Westside Groundwater Basin with the Partner Agencies and the basin would continue to be operated as it is under existing conditions.	• The 16 wells and well facilities would not be constructed or operated. The Westlake Pump Station would not be upgraded. • A new drought water supply may not be developed unless the SFPUC or its wholesale customers pursue other projects.
Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield. The SFPUC would not construct or operate Sites 1 and 4, two of the four wells proposed to be located near Lake Merced. The SFPUC would instead increase Project pumping at Sites 5 through 15 by approximately 20 percent each, to maintain overall yield at 7.2 mgd.	• Pumping near Lake Merced would be reduced by approximately 54 percent compared to the Project. • 14 well facilities would be constructed, rather than 16 wells proposed by the Project. • No well or well facility would be constructed or operated at Sites 1 or 4, and approximately 1.0 mgd of Project pumping proposed at these two wells would not occur. • Approximately 1.0 mgd of Project pumping would be redistributed to wells at Sites 5 through 15. • Pumping at Sites 5 through 15 would increase by approximately 20 percent each compared to the proposed Project. • Well interference impacts on some existing irrigators' wells would be increased.
Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield. The SFPUC would not construct or operate wells at Sites 1 and 4, two of the four sites proposed to be located near Lake Merced. Overall yield would be approximately 6.2 mgd.	• Pumping near Lake Merced would be reduced by approximately 54 percent compared to the Project. • 14 well facilities would be constructed, rather than 16 wells described in the Project. • No well or well facility would be constructed or operated at Sites 1 and 4, and approximately 1.0 mgd of Project pumping proposed at these two wells would not occur. • Overall yield would be reduced from 7.2 mgd to 6.2 mgd, approximately a 14 percent decrease compared to the proposed Project.

TABLE 7-1
Selected CEQA Alternatives

Alternative	How Does the Alternative Differ from the Proposed Project?
Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield. The SFPUC would not construct or operate wells at Sites 7 and 8, two of the seven wells proposed to be located near existing irrigation wells for cemeteries in Colma. The SFPUC would instead increase Project pumping at Sites 1 through 4 and 11 through 15 by approximately 31 percent each, to maintain overall yield at 7.2 mgd.	• Pumping near the existing irrigation wells for cemeteries in Colma would be reduced by approximately 32 percent compared to the Project. • 14 well facilities would be constructed, rather than 16 wells proposed in the Project. • No well or well facility would be constructed or operated at Sites 7 or 8, and approximately 1.2 mgd of Project pumping proposed at these two wells would not occur. • Approximately 1.2 mgd of Project pumping would be redistributed to wells at Sites 1 through 4 and 11 through 15 to maintain yield at 7.2 mgd. • Lake Merced impacts would be increased.
Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield. The SFPUC would not construct or operate wells at Sites 7 and 8, two of the seven sites proposed to be located near existing irrigation wells for cemeteries in Colma. Overall yield would be approximately 6.0 mgd.	• Pumping near the existing irrigation wells for cemeteries in Colma would be reduced by approximately 32 percent compared to the Project. • 14 well facilities would be constructed, rather than 16 wells proposed in the Project. • No well or well facility would be constructed or operated at Sites 7 or 8, and approximately 1.2 mgd of Project pumping proposed at these two wells would not occur. • Overall yield would be reduced from 7.2 mgd to approximately 6.0 mgd, approximately a 16 percent decrease compared to the proposed Project.

7.3.4.1 Alternative 1: No Project Alternative

CEQA Guidelines Section 15126.6(e) requires that EIRs include an evaluation of the No Project Alternative to provide decision-makers the information necessary to compare the relative impacts of approving a project to not approving a project. The No Project Alternative is defined as a continuation of existing conditions, as well as conditions that are reasonably expected to occur in the event that a proposed project is not implemented.

Description of Alternative

In the event that the SFPUC does not implement the GSR Project, no Project facilities would be constructed and the conjunctive use of the South Westside Groundwater Basin, as proposed under the Project, would not occur. Under the No Project Alternative, a GSR dry-year water supply would not be available to the SFPUC, its wholesale customers, or the Partner Agencies, as planned for and approved in the Phased WSIP.

The SFPUC would continue to operate the regional water system, but it would have reduced water supply reliability during dry years under the No Project Alternative compared to the proposed Project. Under the No Project Alternative, regional water system customers would experience water shortages -- and the need to implement water rationing -- more frequently, and water rationing would be more severe; i.e., exceeding 20 percent systemwide rationing, based on hydrologic modeling (San Francisco Planning Department 2008).

In the absence of reliable water service from the SFPUC during dry years, the wholesale customers may pursue other projects, either individually or collectively, to meet their dry-year water needs. However, numerous factors would inhibit the ability of the wholesale customers to address the decreased supply during dry years associated with this alternative, including the following:

- Water demand among all customers is highest when supplies are most constrained, i.e., during dry years, and therefore dry-year water supply is more difficult to secure. Securing water supplies in California is increasingly difficult, particularly in dry years, as overall demand increases and conflicts among competing interests for water supply arise (San Francisco Planning Department 2008).
- A major new water supply project can take as many as 20 to 25 years to complete (Johnson and Loux 2004).
- The SFPUC wholesale customers already have planned for and adopted increased water conservation and recycling initiatives (San Francisco Planning Department 2008).

The ability of the wholesale customers to develop additional dry-year water supplies is uncertain, and further studies would be required to evaluate technical and institutional feasibility. Determining (a) the specific projects that each wholesale customer would pursue, and (b) the likelihood that the wholesale customers could successfully implement the projects is speculative and largely outside the control of the SFPUC.

The basic water management strategies that the wholesale customers could pursue to offset the reduced dry-year water supply under the No Project Alternative involve increasing supply and decreasing demand or increasing rationing during dry years. Potential options associated with these strategies are water purchases or transfers, increased groundwater use, more aggressive water conservation or water recycling, and desalination. However, each of the wholesale customers has already planned for their water supply taking into consideration such programs, and further development of these programs by the wholesale customers may or may not occur for the sake of dry-year supply management.

The WSIP PEIR evaluated water purchases or transfers, increased groundwater use, additional water conservation and water recycling as part of the WSIP and evaluated even further expansion of these programs and local and regional desalination as part of the WSIP alternatives. The WSIP PEIR provides additional detail on supplemental supply options and their associated environmental impacts (San Francisco Planning Department 2008).

Ability of Alternative to Meet Project Objectives

The No Project Alternative would not meet any of the project objectives as it would not result in the coordinated use of SFPUC surface water and groundwater by the Partner Agencies or the in-lieu recharge of the South Westside Groundwater Basin, and it would not provide a new dry-year groundwater supply for SFPUC customers.

Without the Project, the South Westside Groundwater Basin would not be conjunctively managed and the coordinated use of SFPUC surface water and groundwater pumped by the Partner Agencies would not occur. The existing municipal groundwater use by the Partner Agencies would likely continue under the No Project Alternative.

The No Project Alternative would also not support the WSIP goals because it would not provide a dry-year supply to increase water delivery reliability nor would it meet customer water supply needs. The No Project Alternative would not allow the operational flexibility and delivery reliability goals of the WSIP to be met, as fulfillment of the WSIP goals is reliant upon the proposed Project providing 7.2 mgd for up to 7.5 years during a drought.

Environmental Impacts of No Project Alternative Compared to Those of the Proposed Project

The No Project Alternative would avoid all of the construction impacts identified for the GSR Project. The No Project alternative would eliminate the need for construction activities at the GSR facility sites, thereby avoiding all construction impacts identified for the proposed Project, including the significant and unavoidable impacts associated with noise, land use, aesthetics, and hydrology, which, in some instances, may be at least partially reduced by mitigation where feasible (in other instances, feasible mitigations may not exist for reducing some of the impacts identified) (See Section 7.3.2 [Impacts of the Proposed Project]). Other proposed future projects in the GSR Project area may still be implemented. The San Francisco Groundwater Supply (SFGW) Project (cumulative project A-1 through A-6) is one of the projects approved by the SFPUC in 2008 as part of the WSIP, and is currently undergoing project-level environmental review. In addition, the SFPUC Peninsula Pipelines Seismic Upgrade Project (cumulative projects D-1 through D-3), which is also proposed to be implemented under the WSIP and undergoing environmental review, and the PG&E Transmission Pipeline Replacement Project (cumulative project H) could be implemented. While cumulative construction impacts could still occur from these projects, there would be no contribution to the cumulative impacts from the No Project Alternative.

The significant environmental impacts of the No Project Alternative are presented in Table 7-2 (Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project). Because alternatives in general have been selected to reduce groundwater impacts, a more detailed analysis of groundwater impacts is provided than for other impacts.

Indirect or Secondary Impacts. Under the No Project Alternative, the SFPUC could not meet dry-year water supply goals. To meet the dry-year water supply goals, the SFPUC and/or its wholesale customers would likely take action to secure supplemental dry-year supply to make up for drought period supply shortfalls, which could have similar or additional secondary environmental effects. Supplemental dry-year supply options include additional Tuolumne River diversions and water transfers from the Turlock Irrigation District or the Modesto Irrigation District. The WSIP PEIR provides additional detail on supplemental dry-year supply options and their associated environmental impacts (San Francisco Planning Department 2008).

The No Project Alternative could result in secondary effects related to development of drought water supplies. Supplemental water supply options include, for example, water transfers. If the SFPUC and/or its wholesale customers were to pursue supplemental water supplies to compensate for the dry-year shortfall due to the No Project Alternative being selected, the secondary effects could include any or all of the following: construction impacts and operational impacts such as groundwater overdraft, subsidence, seawater intrusion, and water quality effects associated with development of groundwater sources; impacts on fisheries and biological resources, including sensitive species, associated with additional Tuolumne River diversions; and construction impacts and operational impacts on land use, aesthetics, hydrology and water quality, air quality, hazards, and energy associated with development of desalinated water supplies.

7.3.4.2 Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield

Description of Reduce Lake Merced Impacts and Maintain Project Yield Alternative

Alternative 2A was selected for analysis because it would reduce potentially significant biological and water quality impacts associated with declining lake levels at Lake Merced due to Project pumping during dry years, although these impacts have been determined to be less than significant, or less than significant with mitigation (see Impact RE-6 in Section 5.11, Recreation; Impacts BR-6, BR-7, BR-8, BR-9, and C-BR-2 in Section 5.14, Biological Resources; and Impacts HY-9 and C-HY-5 in Section 5.16, Hydrology and Water Quality). Under Alternative 2A, the SFPUC would construct only 14 wells and well facilities (instead of 16 wells under the proposed Project). The 14 wells would be located at the same preferred sites as the Project; however, Alternative 2A would not include a well or well facility at Site 1 in Daly City or Site 4 in unincorporated Broadmoor. Without wells at Sites 1 and 4, pumping would be reduced by approximately 1.0 mgd. To maintain the overall yield at 7.2 mgd, pumping would be redistributed to 11 wells at Sites 5 through 15. Pumping at each of Sites 5 through 15 would increase by approximately 20 percent compared to the proposed Project and production rates of wells at Sites 5 through 15 could support this increased pumping (SFPUC 2012b, 2012c). Pumping at Sites 2 and 3 would not increase under this alternative, because these would become the closest Project wells to Lake Merced and the goal of this alternative is to minimize impacts on Lake Merced, as compared to the proposed Project. Pumping at Site 16 would also not increase under this alternative, as compared to the Project, because groundwater availability is restricted at this location (compared to the other preferred sites). As a result, this alternative would decrease Project pumping near Lake Merced by approximately 54 percent when compared to the Project proposal.

Ability of the Reduce Lake Merced Impacts and Maintain Project Yield Alternative to Meet Project Objectives

Alternative 2A would fully meet the Project objectives. The overall yield would remain at 7.2 mgd, which would meet the Project goal to increase the dry-year and emergency pumping capacity of the South Westside Groundwater Basin by an average annual 7.2 mgd in the event that the 8.5-year design drought was to happen.

Environmental Impacts of the Reduce Lake Merced Impacts and Maintain Project Yield Alternative (Alternative 2A) Compared to Those of the Proposed Project

Construction-related Impacts. Alternative 2A would result in all of the same construction-related impacts as the proposed Project, except for the construction-related impacts associated with construction at Sites 1 and 4. Elimination of Site 1 would eliminate the SU and SUM impacts relative to noise and the SUM impacts relative to land use, as well as all other LSM and LS impacts at that site (see Impacts NO-1 and NO-3 in Section 5.7, Noise and Vibration, and Impact LU-1 in Section 5.2, Land Use). Elimination of Site 4 would eliminate SUM impacts relative to noise and land use (see Impacts NO-1 and NO-3 in Section 5.7, Noise and Vibration, and Impact LU-1 in Section 5.2, Land Use), as well as all other LSM and LS impacts at the site. All other SU and SUM impacts related to noise, land use, and aesthetics would remain as described for the proposed Project. These impacts are described in Chapter 5, Environmental Setting, Impacts and Mitigation Measures. Construction impacts at the remainder of the sites related to cultural resources, transportation and circulation, recreation, utilities and service systems, geology and soils, water quality, and hazards and hazardous materials would be the same as those of the proposed Project, and the same mitigation measures would be required to reduce these impacts to less-than-significant levels.

Operational Impacts. The significant environmental impacts of Alternative 2A are presented in Table 7-2 (Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project). However, because Alternative 2A was selected to reduce groundwater impacts, a more detailed analysis of operational groundwater impacts is provided than for other impacts as compared to the proposed Project. The operational groundwater impacts of the alternatives as compared to the proposed Project are presented below. The information provided comes from the groundwater modeling analysis and other technical studies, as identified below (Kennedy/Jenks 2012b, 2012c).

Production rate of preexisting wells. A 54 percent reduction in pumping near Lake Merced would reduce well interference impacts on the irrigation wells at the Lake Merced Golf Club. This reduced interference, however, would be partially offset by increased pumping at Sites 5, 6, and 7. The 54 percent pumping reduction near Lake Merced attributable to the elimination of Sites 1 and 4, however, would not provide enough change to maintain water levels above the well screens at the Lake Merced Golf Club. As a result, static water levels at the Lake Merced Golf Club wells would still decrease to below the top of the well screen, increasing the risk of well or pump damage. Therefore, the well interference impact on the Lake Merced Golf Club wells would be significant under Alternative 2A, as it would be for the proposed Project. The elimination of pumping at Sites 1 and 4 would have a beneficial effect on the Olympic Club wells and the San Francisco Golf Club wells, compared to the proposed Project because, similar to the proposed Project, both static and pumping groundwater levels would remain above the top of the well screen at these wells under Alternative 2A. Furthermore, these wells have the capacities to meet their peak demand (Fugro 2012b). Therefore, the well interference impact on the Olympic Club wells and the San Francisco Golf Club wells would be less than significant under Alternative 2A, as it would be for the proposed Project.

Increasing pumping at Sites 5 through 15 by 20 percent would increase well interference impacts on the wells at the Colma cemeteries and at the California Golf Club. Under the proposed Project, all irrigation wells at the nine Colma area cemeteries and the California Golf Club would be subject to significant well interference impacts. The increased pumping at Sites 5 through 15 would increase such impacts at these wells by approximately 20 percent. Therefore, the well interference impacts on the Colma cemetery wells and on the California Golf Club wells would be significant and slightly greater under Alternative 2A, than they would be for the proposed Project. Mitigation Measure M-HY-6 (Ensure Existing Irrigators' Wells Are Not Prevented from Supporting Existing or Planned Land Use Due to Project Operation) would reduce the impacts of well interference to *less-than–significant* levels, except that the implementation of the mitigation measure cannot be assured until the existing irrigation well owners have agreed to allow the mitigation to take place on their property, thereby potentially resulting in a *significant and unavoidable impact with mitigation*. Refer to the discussion of Impact HY-6 in Section 5.16, Hydrology and Water Quality, Section 5.16.3.7 (Operation Impacts and Mitigation Measures – Groundwater) where this impact analysis is presented in greater detail.

Land Subsidence. A 54 percent reduction in pumping near Lake Merced would reduce the risk of subsidence near Daly City and the unincorporated community of Broadmoor. A 20 percent increase in pumping at Sites 5 through 15 would increase the risk of subsidence slightly, but would not result in significant impacts, because estimated subsidence would remain below the established thresholds of six inches for structures and drainage patterns, and one foot for floodplains. The maximum expected subsidence under the proposed Project would be 3.4 inches; approximately half of the six-inch threshold. The 20 increase in pumping at Sites 5 through 15 would result in a 20 percent increase in groundwater elevation decline compared to the proposed Project. The method for calculating subsidence indicates that subsidence changes would be proportionately smaller than groundwater elevation changes and, therefore, a 20 percent increase in groundwater level decline would not be expected to increase subsidence to significant levels, because to do so would require almost doubling the amount of subsidence anticipated for the proposed Project (Fugro 2012a). Therefore, subsidence impacts would be slightly greater for Alternative 2A when compared to the proposed Project; however, the impacts would be *less than significant* for both Alternative 2A and the proposed Project.

Seawater Intrusion. Decreasing pumping in the Lake Merced area by 54 percent may reduce the risk of seawater intrusion from the Pacific Ocean slightly. Increasing pumping at Sites 5 through 15 by 20 percent would increase the risk of seawater intrusion from San Francisco Bay. Seawater intrusion has been observed in sediments adjacent to the Bay and is expected to continue into the future. The proposed Project would reduce the risk of seawater intrusion a small amount. Over a long-term average, estimated groundwater elevations at the Bay rise slightly and approximately three acre-feet (af) per year more groundwater is predicted to flow out to the Bay, as compared to modeled existing conditions. (Kennedy/Jenks 2012c)

While there would be an incremental increase in the potential for seawater intrusion due to the 20 percent increase in pumping in Colma, South San Francisco, and San Bruno areas, the magnitude of the increase would be relatively small based on two lines of evidence. First, in general, the San Francisco Bay coast is not particularly susceptible to seawater intrusion due to the presence of the Bay Mud and a subsurface bedrock ridge, both of which provide some protection to the southern portion of the South Westside Basin from potential seawater intrusion from San Francisco Bay (Kennedy/Jenks 2012c). Second, the proposed Project is estimated to increase groundwater flows to the Bay (due to the increase of in-lieu recharge) on the order of two to three af per month at the end of the design drought. For this alternative, the increase in pumping from GSR wells south of Daly City would slightly increase the potential for seawater intrusion from San Francisco Bay as compared to the proposed Project. This is not expected to result in a seawater intrusion impact because it would be similar to the amount of seawater intrusion predicted under modeled existing conditions (SFPUC 2012a). Therefore, potential seawater intrusion impacts would be slightly greater under Alternative 2A; however, the potential impact for both Alternative 2A and the proposed Project would be *less than significant.*

Adverse Effects on Beneficial Uses at Lake Merced. A 54 percent reduction in pumping in the Lake Merced area would result in a 54 percent decrease in the decline of Lake Merced lake levels at the end of the design drought. The proposed Project is expected to result in lake levels that are one foot lower than is predicted to occur under modeled existing conditions at the end of the design drought; under Alternative 2A, this impact would be reduced to approximately 0.5 feet instead of one foot, due to the reduced pumping under this alternative. Because the lake levels under the proposed Project recover more slowly than under modeled existing conditions, the difference between the proposed Project and modeled existing conditions is actually greater several years after the drought than at the end of the drought. Thus, the proposed Project is expected to result in lake levels about four feet lower than under modeled existing conditions after the end of the design drought. With the proposed Project, the lake is expected to recover to a lake level of 0 feet City Datum within 37 months after the drought. Under Alternative 2A, the decline in lake levels (as compared to modeled existing conditions) would be reduced to approximately 2 feet City Datum (instead of 4 feet City Datum under the proposed Project), due to the reduced pumping under this alternative, and the recovery period is expected to be shorter (SFPUC 2012b). During the period following the design drought, when Lake Merced lake levels are recovering, the impact of Alternative 2A on water quality would be *significant*, as it would be for the proposed Project, because, monthly lake level averages would decline below 0 feet City Datum under both the proposed Project (a minimum of -2.5 feet) and this alternative (a minimum of -0.5 feet). Mitigation Measures M-HY-9a (Lake Level Monitoring and Modeling for Lake Merced) and M-HY-9b (Lake Level Management for Lake Merced) would require the SFPUC to develop and implement a lake level monitoring and management program to maintain Lake Merced at water levels similar to conditions that would occur without the Project. The mitigation measures would be effective at reducing impacts of the alternative to less than significant, as it would be for the Project, because it requires the SFPUC to implement lake level management procedures to maintain Lake Merced water levels above 0 feet City Datum. These procedures include continuation of lake-level and groundwater monitoring, additions of supplemental water, if available, or alteration of pumping patterns. Implementation of this measure would ensure that any lake level declines to below 0 feet City Datum as a result of this alternative are short-term and, with the addition of supplemental water or alteration of pumping patterns, this alternative would not result in long-term changes in water quality that would adversely affect the potential beneficial uses of Lake Merced.

Water Quality Standards. A reduction in pumping in the Lake Merced area and an increase in pumping away from Lake Merced would not affect the ability of the SFPUC to provide drinking water that meets drinking water quality standards, because the SFPUC would treat or blend groundwater as necessary to meet primary and secondary water quality standards and because the groundwater to be pumped is not considered vulnerable to soil or groundwater contamination due to the depth of pumping proposed. Therefore, the potential impact of Alternative 2A on drinking water quality would be the same as the proposed Project, which would be *less than significant.*

Under either the Project or Alternative 2A, the SFPUC would supply supplemental surface water to Daly City, and Daly City would decrease groundwater pumping during put years. However, with the reduction in pumping during take years under this alternative, in-lieu recharge could increase compared to the proposed Project, potentially resulting in increased groundwater elevations in the Daly City area after a drought (i.e., Take Years). Such increased groundwater levels would not be expected to rise to the level where existing contaminated plumes are located, because the existing groundwater levels in the Daly City area are very low and would stay very low even with the increased in-lieu recharge. Therefore, the impact of Alternative 2A relative to the potential to mobilize existing areas of contamination due to increasing groundwater levels from in-lieu recharge would be the same as the proposed Project, which would be *less than significant.*

Water Quality Degradation. Decreasing pumping in the Lake Merced area and increasing pumping to the south would not degrade water quality in relation to constituents not currently regulated, because the existing concentration of such non-regulated constituents in the groundwater is lower than what would be likely to cause environmental harm and decreased pumping would not increase or decrease these concentrations. Therefore, potential impacts of Alternative 2A relative to this type of water quality degradation would be *less than significant*, as they would be for the proposed Project.

Groundwater Depletion. Because the overall yield from the Westside Groundwater Basin would be maintained at 7.2 mgd under Alternative 2A, potential impacts on groundwater depletion would be the same as they would be for the proposed Project, which would be *less than significant with mitigation.* Both the proposed Project and Alternative 2A would have the potential to result in depletion of the basin if losses from the SFPUC Storage Account were not considered in the management of pumping. With implementation of Mitigation Measure M-HY-14 (Prevent Groundwater Depletion), pumping would be managed to ensure that GSR wells would only be pumped when there is a positive balance in the SFPUC Storage Account, which would be adjusted for losses from the basin due to leakage.

Reduce Lake Merced Impacts and Maintain Project Yield Alternative Conclusions

Alternative 2A would fully meet the Project objectives and meet the Project goal to increase the dry-year and emergency pumping capacity of the South Westside Groundwater Basin by 7.2 mgd. This alternative would have the same construction-related impacts as the proposed Project, except impacts associated with construction at Sites 1 and 4 would not occur. Operational impacts would be nearly the same as those expected for the proposed Project. A 54 percent reduction in pumping near Lake Merced would reduce well interference on the irrigation wells at the Lake Merced Golf Club; however the reduced well interference at the golf club would be partially offset by increased pumping at Sites 5, 6, and 7, which are within the vicinity of the Lake Merced Golf Club. Increasing pumping at Sites 5 through 15 by 20 percent would increase the potential well interference impacts on the wells at the Colma cemeteries and at the California Golf Club. As a result, well interference impacts would be *significant and potentially unavoidable with mitigation* for both the alternative and the Project, although well interference impacts at some existing wells would be greater under Alternative 2A than the Project. The potential for subsidence impacts and for seawater intrusion would be slightly greater for Alternative 2A when compared to the proposed Project; however impacts would be less than significant for both the alternative and the proposed Project. Declines in water levels in Lake Merced would be slightly less under this alternative; however impacts for both this alternative and the proposed Project would be less than significant with mitigation. Eliminating other wells would not further reduce impacts on Lake Merced water levels because other wells are too far from the lake to have a substantial influence on the lake. Potential impacts on groundwater quality and groundwater depletion would be the same for the proposed Project and this alternative. In any case, this alternative would support the WSIP goals and objectives to provide dry-year and emergency water pumping capacity.

7.3.4.3 Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield

Alternative 2B was selected for analysis because it would reduce significant biological and water quality impacts associated with declining lake levels at Lake Merced due to Project pumping during dry years, but would not include any redistribution of pumping as Alternative 2A does. Under Alternative 2B, the SFPUC would construct only 14 wells and well facilities (instead of 16 wells under the proposed Project). The 14 wells would be located at the same preferred sites as the Project; however, Alternative 2B would not include a well or well facility at Site 1 in Daly City or at Site 4 in unincorporated Broadmoor. Without wells at Sites 1 and 4, Project pumping would be reduced by approximately 1.0 mgd and the overall Project yield would be 6.2 mgd. The alternative would also decrease pumping near Lake Merced by approximately 54 percent (as would Alternative 2A).

Ability of Alternative to Meet Project Objectives Compared to the Proposed Project

Alternative 2B would reduce pumping by 1.0 mgd; therefore, the alternative would meet most, but not all, of the Project objectives. This alternative would allow for the conjunctive use of the South Westside Groundwater Basin, and it would provide supplemental SFPUC surface water to Partner Agencies during normal and wet years to allow for in-lieu recharge of the Basin, albeit reduced by 1 mgd, as compared to the proposed Project. The alternative would not meet the objective of increasing the SFPUC's dry-year and emergency pumping capacity by 7.2 mgd; it would provide a new dry-year groundwater supply though not at the same volume as described in Section 7.3.1 (Approach to Alternatives Selection) or in the adopted WSIP goals. Therefore, in order to meet the WSIP goal of limiting rationing to a systemwide maximum of 20 percent during an 8.5-year drought, if this alternative were implemented, the SFPUC or its wholesale customers could decide to pursue additional projects such as water transfers to increase dry-year and emergency pumping capacity by 7.2 mgd.

The alternative would also not meet the project objective of providing an emergency supply, to be used in the event of a catastrophic emergency that would affect the other sources of supply for the regional water system. Therefore, the reduction in yield with Alternative 3B would limit the regional water system's ability to meet the WSIP goal of seismic and delivery reliability, adopted as part of approval of the WSIP under SFPUC Resolution 08-0200. Per the adopted resolution, the SFPUC will reevaluate 2030 demand projections, regional water system purchase requests, and water supply options by 2018. If this alternative were adopted, the up to 1.2-mgd reduction in drought-year water supply would be included as part of the reevaluation and taken into consideration as a part of the separate SFPUC decision regarding water deliveries after 2018. With the reduction in yield from this alternative, the SFPUC may need to revise the WSIP goals and objectives or develop additional water supply projects depending on demand projections.

Environmental Impacts of Alternative 2B

The significant environmental impacts of Alternative 2B are presented in Table 7-2 (Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project). However, because Alternative 2B was evaluated for its ability to reduce groundwater impacts, a more detailed analysis of operational groundwater impacts is provided than for other impacts, as compared to the proposed Project. The operational groundwater impacts of this alternative, as compared to the proposed Project, are presented below. The information provided comes from the groundwater modeling analysis and other technical studies, as identified below (Kennedy/Jenks 2012a, 2012b).

Production rate of preexisting wells. A 54 percent reduction in pumping near Lake Merced would reduce well interference impacts on the irrigation wells at the Lake Merced Golf Club. The Project is predicted to lower static water levels in the Lake Merced Golf Club Well #3 by 85 feet at the end of the design drought, from 271 feet below ground surface (bgs) to 356 feet bgs (see Table 5.16-11 [Estimated Static and Pumping Depth to Water Level at the End of the Design Drought] in Section 5.16, Hydrology and Water Quality). Assuming a linear relationship between pumping and water level, a 54 percent reduction in nearby pumping would lower static water levels by 46 percent of 85 feet (i.e., by 39 feet). The static water level in the Lake Merced Golf Club Well #3 at the end of the design drought is therefore estimated to be 310 feet bgs, which would be below the top of the screen at 294 feet bgs. Therefore, even with the 54 percent pumping reduction at Sites 1 and 4, static water levels at the Lake Merced wells would decrease to below the top of the well screen (albeit approximately 39 feet higher than is predicted to result with the proposed Project), which would reduce but not eliminate the risk of well or pump damage. Therefore, the well interference impact on the Lake Merced Golf Club wells would also be *significant* under Alternative 2B, as it would be for the proposed Project.

The elimination of pumping at Sites 1 and 4 would reduce the Project's potential well interference impacts on the Olympic Club wells and the San Francisco Golf Club wells. The Project would lower static water levels in both Olympic Club Well #8 and Olympic Club Well #9 by 14 feet, from 122 feet bgs to 136 feet bgs at the end of the design drought (see Table 5.16-11 [Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought] in Section 5.16, Hydrology and Water Quality). Assuming a linear relationship between pumping and water level, a 54 percent reduction in nearby pumping would lower static water levels by 46 percent of 14 feet (i.e., by 6 feet). The static water level in both of the Olympic Club Wells at the end of the design drought is therefore estimated to be 128.4 feet bgs, which would be above the top of the screen at 260 feet bgs. Table 5.16-12 (Estimated Pump Discharge Rate at the End of the Design Drought) shows that the Project is expected to lower static water levels in the San Francisco Golf Club Well #2 by 14 feet, from 182 feet bgs to 196 feet bgs. Assuming a linear relationship between pumping and water level, a 54 percent reduction in nearby pumping would lower static water levels by 46 percent of 14 feet (i.e., by 6 feet). The static water level in both of the Olympic Club Wells at the end of the design drought is therefore estimated to be 188 feet bgs, which would be above the top of the screen at 360 feet bgs. Therefore, similar to the proposed Project, both static and pumping groundwater levels would remain above the top of the well screen at these wells under Alternative 2B. Furthermore, these wells have the capacities to meet peak their demand (see Impact HY-6 in Section 5.16, Hydrology and Water Quality). Therefore, the potential well interference impact on the Olympic Club wells and the San Francisco Golf Club wells would also be *less than significant* under Alternative 2B, as it would be for the proposed Project.

Land Subsidence. A 54 percent reduction in pumping near Lake Merced would reduce the risk of subsidence near Daly City and the unincorporated community of Broadmoor, as compared to the proposed Project. Because pumping would not be increased in Colma, South San Francisco and San Bruno, this alternative would not change subsidence impacts in these areas. Therefore, subsidence impacts would also be *less than significant* under Alternative 2B, as they would be for the proposed Project.

Seawater Intrusion. Decreasing pumping in the Lake Merced area by 54 percent would correspondingly reduce the risk of seawater intrusion from the Pacific Ocean, as compared to the Project. Therefore, seawater intrusion impacts would also be *less than significant* under Alternative 2B, as they would be for the proposed Project.

Adverse Effects on Beneficial Uses at Lake Merced. A 54 percent reduction in pumping in the Lake Merced area would result in a 54 percent decrease in the decline of Lake Merced lake levels at the end of the design drought. The proposed Project is expected to result in lake levels that are 1 foot lower than predicted under modeled existing conditions at the end of the design drought; under Alternative 2B, this impact would be reduced by 54 percent to approximately 0.5 feet instead of 1 foot, given that the pumping from Sites 1, 2, 3, and 4 would be within 1.3 miles of Lake Merced, whereas the next closest Project well would be over 2 miles from the lake, and Sites 1 and 4 constitute 54 percent of the proposed pumping at Sites 1, 2, 3, and 4 (SFPUC 2012b, 2012c). Because the lake levels under the proposed Project recover more slowly than under modeled existing conditions, the difference between the proposed Project and modeled existing conditions is actually greater several years after the drought than at the end of the drought. Thus, the proposed Project is also expected to result in lake levels about 4 feet lower than predicted under modeled existing conditions after the design drought, with lake levels gradually increasing over the 37-month period during which the lake is recovering from the drought; under Alternative 2B, the decline in lake levels (as compared to modeled existing conditions) would be reduced to approximately 2 feet instead of 4 feet (SFPUC 2012b, 2012c). Minimum monthly average lake levels are predicted to be -2.5 feet City Datum due to the Project, and approximately -0.5 feet for the alternative, both of which are below 0 feet, which is the threshold used by this EIR for determining significant water quality impacts on Lake Merced. Therefore, during the period following the design drought, until Lake Merced lake levels recover to a level of 0 feet City Datum, the impact of Alternative 2B on water quality would be *significant*, as it would be for the proposed Project. However, implementation of Mitigation Measures M-HY-9a (Lake Level Monitoring and Modeling for Lake Merced) and M-HY-9b (Lake Level Management for Lake Merced)would reduce the water quality impact of this alternative on Lake Merced to *less-than-significant* levels, as it would for the Project, through development and implementation of lake level monitoring and management procedures to maintain Lake Merced at water levels similar to conditions that are predicted to occur without the Project.

Water Quality Standards. A reduction in pumping in the Lake Merced area would not affect the ability of the SFPUC to provide drinking water that meets drinking water quality standards, because the SFPUC would treat or blend groundwater as necessary to meet primary and secondary water quality standards and because the groundwater to be pumped is not considered vulnerable to soil or groundwater contamination due to the depth of pumping proposed. Therefore, the impact of Alternative 2B on drinking water quality would be *less than significant*, as it would be for the proposed Project.

Because groundwater levels that would result from this alternative would not be expected to rise more than they would from the proposed Project, due to the reduced pumping, the impact of Alternative 2B on the potential to mobilize existing areas of contamination would be *less than significant*, as it would be for the proposed Project.

Water Quality Degradation. Decreasing pumping in the Lake Merced area would not affect water quality degradation from constituents not currently regulated because the existing concentration of such non-regulated constituents in the groundwater is lower than what would be likely to cause environmental harm and decreased pumping would not increase or decrease these concentrations. Therefore, potential impacts of Alternative 2B relative to water quality degradation would be *less than significant*, as they would be for the proposed Project (Kennedy/Jenks 2012d).

Groundwater Depletion. Because the overall yield from the Westside Groundwater Basin would be reduced to 6.2 mgd, potential impacts on groundwater depletion resulting from Alternative 2B would be less than expected for the proposed Project. However, impacts on groundwater depletion under both the alternative and the proposed Project would be *less than significant with mitigation.* Both the proposed Project and Alternative 2B would have the potential to result in depletion of the basin if losses from the SFPUC Storage Account were not considered in the management of pumping. With implementation of Mitigation Measure M-HY-14 (Prevent Groundwater Depletion), pumping would be managed to ensure that GSR wells would only be pumped when there is a positive balance in the SFPUC Storage Account, which would be adjusted for losses from the basin due to leakage.

Reduce Lake Merced Impacts and Reduce Project Yield Alternative Conclusions

Alternative 2B would meet most, but not all, of the Project goals and objectives. It would provide for the conjunctive management of the South Westside Groundwater Basin, and it would provide supplemental SFPUC surface water to Partner Agencies in normal and wet years, albeit reduced by 1 mgd, as compared to the proposed Project. Alternative 2B would also provide a new dry-year groundwater supply though not at the same volume as described in Section 7.3.1 (Approach to Alternatives Selection) or in the adopted WSIP goals. Therefore, in order to meet the WSIP goal of limiting rationing to a systemwide maximum of 20 percent during an 8.5-year drought, the SFPUC or its wholesale customers could decide to pursue additional projects such as water transfers so that, combined with this alternative, it could increase its dry-year and emergency pumping capacity by 7.2 mgd.

This alternative would have the same construction-related impacts as the proposed Project, except impacts associated with construction at Sites 1 and 4 would not occur.

The alternative would decrease pumping near Lake Merced by approximately 54 percent; however the operational impacts would be similar to those expected for the proposed Project. A 54 percent decrease in pumping near Lake Merced would result in groundwater levels that would have similar or slightly less well interference impacts on existing irrigation wells as compared to the Project. However, this alternative would have *significant and potentially unavoidable* well interference impacts, which would be the same level of significance for this impact as with the proposed Project. Alternative 2B would reduce the potential for subsidence and seawater intrusion as compared to the proposed Project; however both the proposed Project and Alternative 2B would result in less than significant impacts relative to subsidence and seawater intrusion. Water levels in Lake Merced would decrease slightly less under the alternative; however such impacts resulting from this alternative and the proposed Project would be less than significant following implementation of mitigation. Eliminating other wells would not further reduce impacts on Lake Merced water levels because other wells are too far from the lake to have a substantial influence on the lake. Potential impacts on groundwater quality and groundwater depletion would be the same for the proposed Project and the alternative (less than significant and less than significant with mitigation, respectively).

7.3.4.4 Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield

Alternative 3A was selected for analysis because it would reduce the significant well interference impacts of the Project during dry years at existing irrigation wells that are located at the Colma-area cemeteries. Under Alternative 3A, the SFPUC would construct only 14 wells and well facilities (instead of 16 wells under the proposed Project). The 14 wells would be located at the same preferred sites as the Project; however, Alternative 3A would not include a well or well facility at Sites 7 or 8 in Colma. Without wells at Sites 7 and 8, Project pumping would be reduced by approximately 1.2 mgd. To maintain the overall yield at 7.2 mgd, pumping would be redistributed to nine wells at Sites 1 through 4 and Sites 11 through 15. Project pumping at each of these sites would increase by approximately 31 percent compared to the proposed Project. Pumping at Sites 5, 6, 9, and 10 would be the same as the Project, because they are near Colma; pumping at Site 16 would also not increase under this alternative, as compared to the Project, because groundwater availability is restricted at this location (compared to the other preferred sites). The alternative would decrease pumping in the Colma area by approximately 32 percent.

Ability of Alternative to Meet Project Objectives Compared to the Proposed Project

Alternative 3A would fully meet the Project objectives. The overall yield would be at 7.2 mgd, which would meet the Project goal to increase the dry-year and emergency pumping capacity of the South Westside Groundwater Basin by 7.2 mgd.

Environmental Impacts of Alternative 3A

The significant environmental impacts of Alternative 3A are presented in Table 7-2 (Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project). However, because Alternative 3A was evaluated for its ability to reduce groundwater impacts, a more detailed analysis of operational groundwater impacts is provided than for other impacts, as compared to the proposed Project. The operational groundwater impacts of the alternatives as compared to the proposed Project are presented below. The information provided comes from the groundwater modeling analysis and other technical studies, as identified below (Kennedy/Jenks 2012a, 2012b).

Production rate of preexisting nearby wells. A 32 percent reduction in pumping near Colma-area existing irrigation wells would reduce well interference impacts on these wells.

The Project is predicted to lower static water levels in the Eternal Home Cemetery well by 105 feet, reducing static water levels to below the top of the well screen at the end of the design drought (see Table 5.16-11 [Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought] in Section 5.16, Hydrology and Water Quality). Assuming a linear relationship between pumping and water level, a 32 percent reduction in nearby pumping would lower static water levels by 68 percent of 105 feet (i.e., by 71 feet). This same table shows that, at the end of the design drought, the Project is predicted to lower static water levels in the Woodlawn Cemetery Well by 116 feet; and lower static water levels in the Italian Cemetery Well by 110 feet. Assuming a linear relationship between pumping and water level, a 32 percent reduction in nearby pumping would lower static water levels by 68 percent of 116 feet (i.e., by 79 feet in the Woodlawn Cemetery Well); and by 68 percent of 110 feet (i.e., by 75 feet in the Italian Cemetery Well). With these estimated lowered static groundwater levels at the end of the design drought, the static water levels at the Eternal Home Cemetery well, Woodlawn Cemetery well, and Italian Cemetery well would fall below the top of the well screens under Alternative 3A. As a result, the well interference impact on these wells would also be *significant* under Alternative 3A, as it would be for the proposed Project.

Table 5.16-12 (Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought) also shows that, at the end of the design drought, the Project is predicted to lower pumping water levels in the Holy Cross Cemetery Well #4 by 81 feet. The same table shows that, at the end of the design drought, the Project is predicted to lower pumping water levels in the Hills of Eternity Cemetery Well by 89 feet. Assuming a linear relationship between pumping and water level, a 32 percent reduction in nearby pumping would lower pumping water levels by 68 percent of 81 feet (i.e., by 55 feet in the Holy

Cross Cemetery Well #4); and by 68 percent of 89 feet (i.e., by 61 feet in the Hills of Eternity Cemetery Well). With these estimated lowered groundwater levels at the end of the design drought, the static water levels at the Holy Cross Cemetery well #4 and at the Hills of Eternity Cemetery well would fall below the top of the well screen under Alternative 3A; As a result, the well interference impact on these wells would be *significant* under Alternative 3A, as it would be for the proposed Project.

The Olivet Memorial Park well is expected to have just enough capacity to meet its expected demands, as predicted under modeled existing conditions (see Impact HY-6 in Section 5.16, Hydrology and Water Quality). Consequently, any lowering of groundwater levels at this well would likely result in this well having insufficient capacity to meet its expected demands. Therefore, even with the reduced pumping at Sites 7 and 8, the well interference impact on the Olivet Memorial Park well under Alternative 3A would be *significant*, as it would be for the proposed Project.

The Project is predicted to lower pumping water levels in the Holy Cross Cemetery Well #1 by 86 feet, at the end of the design drought (see Table 5.16-11 [Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought] in Section 5.16, Hydrology and Water Quality). Assuming a linear relationship between pumping and water level, a 32 percent reduction in pumping by eliminating pumping at GSR Sites 7 and 8 would lower pumping water levels by 68 percent of 86 feet (i.e., by 58 feet). If pumping were not increased at any other wells in the vicinity, the pumping water level in the Holy Cross Cemetery Well #1 at the end of the design drought is predicted to be slightly above the top of the well screen. However, because the pumping groundwater level would be very close to the top of the well screen, the additional drawdown from the increased pumping at Sites 11 and 12, as per Alternative 3A, is projected to drop the pumping water level below the top of the well screen. Therefore, the well interference impact on this well would be *significant* under Alternative 3A, as it would be for the proposed Project.

Table 5.16-11 (Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought) also shows that, at the end of the design drought, the Project is predicted to lower pumping water levels in the Home of Peace Well by 81 feet. Therefore, under the Project, the pumping water level is predicted to be below the top of the screen at the end of the design drought. Assuming a linear relationship between pumping and water level, a 32 percent reduction in nearby pumping would lower pumping water levels by 68 percent of 81 feet (i.e., by 55 feet). The pumping water level in the Home of Peace Well at the end of the design drought is predicted to be sufficiently above the top of the well screen. Accordingly, the reduced pumping at Sites 7 and 8 is estimated to result in both pumping and static groundwater levels above the top of the well screen at the Home of Peace Cemetery well. The pumping capacities of this well under Alternative 3A are therefore estimated to meet peak demand even when Project pumping is at a maximum (see Impact HY-6 in Section 5.16, Hydrology and Water Quality). As a result, the well interference impact on the Home of Peace Cemetery well would be *less than significant* under Alternative 3A, while the impact of the proposed Project at this well would be *significant*.

Increasing pumping at Sites 1 through 4 by 31 percent would increase well interference impacts at the San Francisco Golf Club, Olympic Club, and Lake Merced Golf Club, as compared to the Project. The Project is predicted to lower pumping water levels in the San Francisco Golf Club Well #2 by 11 feet at the end of the design drought. Assuming a linear relationship between pumping and water level, a 31 percent increase in nearby pumping would lower pumping water levels by an additional 31 percent over the 11 feet of anticipated drawdown (i.e., by an additional 3 feet). The pumping water level in the San Francisco Golf Club Well #2 at the end of the design drought is predicted to be sufficiently above the top of the screen. Therefore, at the end of the design drought both static and pumping groundwater levels would remain above the top of the well screens in the San Francisco Golf Club Well #2 under Alternative 3A. Furthermore, as shown above, the drop in groundwater levels estimated to be caused by the 31 percent increased pumping (as compared to the Project) would be less than 3.5 feet, and therefore would cause a negligible change in the capacity of the existing irrigation wells in this region. As a result, the well interference impact on the San Francisco Golf Club Well #2 would be *less than significant* under Alternative 3A, as it would be for the Proposed Project.

Table 5.16-11 (Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought) also shows that at the end of the design drought the Project is predicted to lower pumping water levels in the Olympic Club Well #8 by 10 feet; and lower pumping water levels in the Olympic Club Well #9 by 4 feet. Assuming a linear relationship between pumping and water level, a 31 percent increase in pumping at Sites 1 through 4 would lower pumping water levels by an additional 31 percent over the 10 feet of anticipated drawdown (i.e., by an additional 3 feet) at Olympic Club Well #8; and lower pumping water levels by an additional 31 percent of the 4 feet of anticipated drawdown (i.e., by an additional 1 foot) at Olympic Club Well #9. The pumping water level in the Olympic Club Well #8 at the end of the design drought is predicted to be just above the top of the screen; and the pumping water level in the Olympic Club Well #9 at the end of the design drought is predicted to be above the top of the screen. Neither well would be influenced by pumping from any other GSR wells. Therefore, both static and pumping groundwater levels at the end of the design drought are estimated to remain above the top of the well screens in the Olympic Club Wells #8 and #9 under Alternative 3A. Furthermore, as shown above, the drop in groundwater levels that estimated to be caused by the 31 percent increased pumping (as compared to the Project) is less than 3.5 feet, which would therefore cause a negligible change in the capacity of the existing irrigation wells in this area. As a result, the well interference impact on the Olympic Club Wells #8 and #9 would be *less than significant* under Alternative 3A, as it would be for the Proposed Project.

Table 5.16-11 (Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought) also shows that at the end of the design drought the Project is predicted to lower static water levels in the Lake Merced Golf Club Well #3 by 85 feet. Assuming a linear relationship between pumping and water level, a 31 percent increase in nearby pumping would lower static water levels by an additional 31 percent of the 85 feet of anticipated drawdown (i.e., by an additional 26 feet). The static water level in the Lake Merced Golf Club Well #3 at the end of the design drought is predicted to be below the top of the screen. As a result, the well interference impact on the Lake Merced Golf Club well would be *significant*, as it would be for the proposed Project.

Table 5.16-11 (Estimated Static and Pumping Depth to Water at the End of the Design Drought) also shows that at the end of the design drought the Project is predicted to lower static water levels in the California Golf Club Well #7 by 168 feet, and to lower static water levels in the California Golf Club Well #8 by 169 feet. Assuming a linear relationship between pumping and water level, a 31 percent increase in pumping at Sites 11 through 15 would lower static water levels by an additional 31 percent of the 168 feet of anticipated drawdown at the California Golf Club Well #7 (i.e., by an additional 52 feet); and would lower static water levels by an additional 31 percent of the 169 feet of anticipated drawdown at the California Golf Club Well #8 (i.e., by an additional 52 feet). The static water level in the California Golf Club Well #7 at the end of the design drought is predicted to be below the top of screen; and the static water level in the California Golf Club Well #8 at the end of the design drought is predicted to be below the top of screen. As a result, the well interference impact on these wells would be *significant* under Alternative 3A, as it would be for the proposed Project.

However, implementation of Mitigation Measure M-HY-6 would reduce these impacts of well interference to *less-than-significant* levels, by either increasing irrigation efficiency, modifying irrigation operations, or undertaking other actions detailed in Mitigation Measure M-HY-6 (Ensure Existing Irrigators' Wells Are Not Prevented from Supporting Existing or Planned Land Use Due to Project Operation). Nevertheless, the implementation of this mitigation measure cannot be assured at this time, until the existing irrigation well owners have agreed to allow the mitigation to take place on their property and, therefore, the impact is determined to be *significant and potentially unavoidable with mitigation*.

Land Subsidence. A 32 percent reduction in pumping near Colma would reduce the risk of subsidence in that area, as compared to the Project. A 31 percent increase in pumping at Sites 1 through 4 and 11 through 15 would increase the risk of subsidence slightly, but would not result in significant impacts, because estimated subsidence would remain below the established thresholds of 6 inches for structures and drainage patterns; and one foot for floodplain. The maximum expected subsidence under the proposed Project would be 3.4 inches; approximately half of the 6-inch threshold. The 31 percent increase in pumping at Sites 1 through 4 and 11 through 15 would result in a 31 percent increase in groundwater elevation decline compared to the proposed Project. The method for calculating subsidence indicates that subsidence changes would be proportionately smaller than groundwater elevation changes and, therefore, a 31 percent increase in groundwater level decline would not be expected to increase subsidence to significant levels, because to do so would require almost doubling the amount of subsidence anticipated for the proposed Project (Fugro 2012a). Therefore, subsidence impacts would be *less than significant* under Alternative 3A, as they would be for the proposed Project.

Seawater Intrusion. Decreasing pumping in the Colma area by 32 percent and increasing pumping at Sites 11 through 15 in South San Francisco and San Bruno by 31 percent would accordingly increase the risk of seawater intrusion from the San Francisco Bay, as compared to the Project. Seawater intrusion has been observed in sediments adjacent to the Bay and is expected to continue into the future. The proposed Project would reduce the risk of seawater intrusion a small amount. Over the 47 years simulated by the West Basin Model, estimated groundwater elevations at the Bay under Project conditions rise slightly (Table 10.3-2 in Kennedy/Jenks 2012c), and approximately 3 af per year more groundwater is predicted to flow out to the Bay than under modeled existing conditions (Table 10.3-5 in Kennedy/Jenks 2012c).

While there would be an incremental increase in the potential for seawater intrusion due to the 31 percent increase in pumping in the South San Francisco and San Bruno areas, the magnitude of the increase would be relatively small based on two lines of evidence. First, in general, the San Francisco Bay coast has physical controls that limit the rate of seawater intrusion, including the presence of the Bay Mud and a subsurface bedrock ridge, both of which provide some protection to the southern portion of the South Westside Basin (Kennedy/Jenks 2012c). Second, the proposed Project is estimated to increase groundwater flows to the Bay (due to the increase of in-lieu recharge) by about 2 to 3 af per month at the end of the design drought. For Alternative 3A, the increase in pumping from GSR wells at Sites 11 through 15 would slightly increase the potential for seawater intrusion from San Francisco Bay as compared to the proposed Project. This is not expected to result in a seawater intrusion impact because it would be similar to the amount of seawater intrusion predicted under modeled existing conditions (SFPUC 2012a). Therefore, seawater intrusion impacts would be *less than significant* under Alternative 3A, as they would be for the proposed Project.

Adverse Effects on Beneficial Uses at Lake Merced. A 31 percent increase in pumping in the Lake Merced area would result in a 31 percent increase in the decline of Lake Merced lake levels at the end of the design drought, because GSR Sites 1, 2, 3, and 4 would be within 1.3 miles of Lake Merced whereas the next closest GSR sites would be over 2 miles from the lake, and this alternative proposes to increase pumping at GSR Sites 1, 2, 3, and 4 by 31 percent. The proposed Project is expected to result in lake levels that are 1 foot lower than is predicted to occur under modeled existing conditions at the end of the design drought (SFPUC 2012b); under Alternative 3A, this impact would be increased to approximately 1.3 feet (instead of 1 foot under the proposed Project), due to the 31 percent increase in pumping in the Lake Merced area. Because recovery in lake levels is slower with the Project than under modeled existing conditions, the proposed Project is expected to result in lake levels about 4 feet lower than what is expected under modeled existing conditions after recovery from the design drought. With the proposed Project, the lake is expected to recover to a lake level of 0 feet City Datum within 37 months after the drought. Under Alternative 3A, this impact would be increased to approximately 5.2 feet (instead of 4 feet under the proposed Project), due to the increased pumping in this area during the drought, and the recovery period is expected to be longer. Monthly lake level averages are predicted to decline below 0 feet City Datum under both the proposed Project (a minimum of -2.5 feet) and this alternative (a minimum of -3.7 feet). Therefore, during the period following the design drought, when Lake Merced lake levels are recovering, the impact of Alternative 3A on water quality would be *significant*, which would be a greater impact under this alternative than for the proposed Project. However, implementation of Mitigation Measures M-HY-9a (Lake Level Monitoring and Modeling for Lake Merced) and M-HY-9b (Lake Level Management for Lake Merced) would reduce the water quality impacts of this alternative to *less-than-significant* levels, because it requires the SFPUC to implement lake level management procedures to maintain Lake Merced water levels above 0.0 feet. Nevertheless, the impact would be greater under Alternative 3A, requiring more supplemental water, redistribution of pumping, or discontinued pumping than under the proposed Project.

Water Quality Standards. A reduction in pumping in the Colma area and an increase in pumping away from Colma would not affect the ability of the SFPUC to provide drinking water that meets drinking water quality standards, because the SFPUC would treat or blend groundwater as necessary to meet primary and secondary water quality standards and because the groundwater to be pumped is not considered vulnerable to soil or groundwater contamination due to the depth of pumping proposed. Therefore, the potential impact of Alternative 3A on drinking water quality would be *less than significant*, as it would be for the proposed Project.

Because in-lieu recharge does not occur in the Colma area (because none of the Partner Agencies have wells in Colma) where pumping would decrease, Alternative 3A is not expected to result in higher groundwater levels than those expected under modeled existing conditions. Therefore, the impact of Alternative 3A on the potential to mobilize existing areas of contamination due to increasing groundwater levels from in-lieu recharge would be *less than significant*, as it would be for the proposed Project.

Water Quality Degradation. Decreasing pumping in the Colma area and increasing pumping to the north and south would not affect water quality degradation from constituents not currently regulated because the existing concentration of such non-regulated constituents in the groundwater is lower than what would be likely to cause environmental harm, and decreased pumping would not increase or decrease these concentrations. Therefore, potential impacts of Alternative 3A relative to water quality degradation would be the same as the proposed Project, which would be *less than significant*.

Groundwater Depletion. Because the overall yield from the Westside Groundwater Basin would be maintained at 7.2 mgd under Alternative 3A, potential impacts on groundwater depletion would be *less than significant with mitigation*, as they would be for the proposed Project. Both the proposed Project and Alternative 2A would have the potential to result in depletion of the basin if losses from the SFPUC Storage Account were not considered in the management of pumping. With implementation of Mitigation Measure M-HY-14 (Prevent Groundwater Depletion), pumping would be managed to ensure that GSR wells would only be pumped when there is a positive balance in the SFPUC Storage Account, which would be adjusted for losses from the basin due to leakage.

Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield Conclusions

Alternative 3A would fully meet the Project objectives and meet the Project goal to increase the dry-year and emergency pumping capacity of the South Westside Groundwater Basin by 7.2 mgd. This alternative would have the same construction-related impacts as the proposed Project except impacts associated with construction at Sites 7 and 8, including the significant and unavoidable aesthetic impact at Site 7, would not occur. Operational impacts would be nearly the same as those expected for the proposed Project. A 32 percent reduction in pumping near the Colma-area existing irrigation wells from this alternative as compared to the proposed Project would reduce well interference on the existing wells; however, well interference would still be significant for Alternative 3A as it would for the proposed Project. The potential for subsidence impacts and for seawater intrusion would be slightly greater for Alternative 3A when compared to the proposed Project; however impacts would be *less than significant* for both the alternative and the proposed Project. Potential impacts on Lake Merced water levels would be slightly greater for Alternative 3A than for the proposed Project, prior to mitigation, but as mitigated, both would result in less-than-significant impacts on the water quality of Lake Merced (even though, under Alternative 3A, more supplemental water, redistribution of pumping, or discontinued pumping would be required to mitigate such impacts, as compared to the proposed Project). Potential impacts on groundwater quality and groundwater depletion would be the same for the proposed Project and this alternative.

7.3.4.5 *Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield*

Alternative 3B was selected for analysis because it would reduce the significant well interference impacts of the Project at existing irrigation wells for cemeteries in the Colma area due to Project pumping during dry years, but it would not include any redistribution of pumping as Alternative 3A does (in order to provide the SFPUC with a dry-year and emergency pumping capacity of 7.2 mgd). Under Alternative 3B, the SFPUC would construct only 14 wells and well facilities (instead of 16 wells under the proposed Project). The 14 wells would be located at the same preferred sites as the Project; however, Alternative 3B would not include a well or well facility at Sites 7 or 8 in Colma. Without wells at Sites 7 and 8, pumping would be reduced by approximately 1.2 mgd, and the overall yield would be 6.0 mgd. The alternative would also decrease pumping near Colma by approximately 32 percent (as would Alternative 3A).

Ability of Alternative to Meet Project Objectives Compared to Proposed Project

Alternative 3B would reduce pumping by 1.2 mgd; therefore, the alternative would meet most, but not all, of the Project objectives. This alternative would allow for the conjunctive use of the South Westside Groundwater Basin, and it would provide supplemental SFPUC surface water to Partner Agencies during normal and wet years to allow for in-lieu recharge of the Basin, albeit reduced by 1.2 mgd, as compared to the proposed Project. The alternative would not meet the objective of increasing the SFPUC's dry-year and emergency pumping capacity by 7.2 mgd; it would also provide a new dry-year groundwater supply though not at the same volume as under the proposed Project. Therefore, in order to meet the WSIP goal of limiting rationing to a systemwide maximum of 20 percent during an 8.5 year drought, if this alternative were implemented, the SFPUC or its wholesale customers could decide to pursue additional projects (e.g., water transfers) to increase dry-year and emergency pumping capacity up to 7.2 mgd.

The alternative would also not meet the project objective of providing an emergency supply, to be used in the event of a catastrophic emergency that would affect the other sources of supply for the regional water system. Therefore, the reduction in yield with Alternative 3B would limit the regional water system's ability to meet the WSIP goal of seismic and delivery reliability, adopted as part of approval of the WSIP under SFPUC Resolution 08-0200. Per the adopted resolution, the SFPUC will reevaluate 2030 demand projections, regional water system purchase requests, and water supply options by 2018. If this alternative were adopted, the up to 1.2-mgd reduction in drought-year water supply would be included as part of the reevaluation and taken into consideration as a part of the separate SFPUC decision regarding water deliveries after 2018. With the reduction in yield from this alternative, the SFPUC may need to revise the WSIP goals and objectives or develop additional water supply projects depending on demand projections.

Environmental Impacts of Alternative 3B

The significant environmental impacts of Alternative 3B are presented in Table 7-2 (Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project). However, because Alternative 3B was selected for analysis to reduce groundwater impacts, a more detailed analysis of operational groundwater impacts is provided than for other impacts as compared to the proposed Project. The operational groundwater impacts of the alternatives as compared to the proposed Project are presented below. The information provided comes from the groundwater modeling analysis and other technical studies, as identified below (Kennedy/Jenks 2012a, 2012b).

Production rate of preexisting nearby wells. A 32 percent reduction in pumping near Colma-area existing irrigation wells, as associated with this alternative, would reduce well interference impacts on those wells.

At the end of the design drought, the Project is predicted to lower static water levels by 105 feet in the Eternal Home Cemetery well; by 116 feet in the Woodlawn Cemetery Well; and by 110 feet in the Italian Cemetery Well (see Table 5.16-11 [Estimated Static and Pumping Depth Levels to Water at the End of the Design Drought] in Section 5.16, Hydrology and Water Quality). Assuming a linear relationship between pumping and water level, a 32 percent reduction in nearby pumping would lower static water levels by 68 percent of 105 feet (i.e., by 71 feet), in the Eternal Home Cemetery well; by 68 percent of 116 feet (i.e., by 79 feet) in the Woodlawn Cemetery Well; and by 68 percent of 110 feet (i.e., by 75 feet) in the Italian Cemetery Well. The static water levels in the Eternal Home Cemetery Well, Woodlawn Cemetery Well and Italian Cemetery Well at the end of the design drought are predicted to be below the top of the well screens. Therefore, the reduced pumping is expected to result in static groundwater levels at these three cemetery wells falling to below the top of the well screens under Alternative 3B. As a result, the well interference impact on these wells would be *significant* under Alternative 3B, as it would be for the proposed Project.

Table 5.16-11 (Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought) also shows that, at the end of the design drought, the Project is predicted to lower pumping water levels in the Holy Cross Cemetery Well #4 by 81 feet. The same table shows that, at the end of the design drought, the Project is predicted to lower pumping water levels in the Hills of Eternity Cemetery Well by 89 feet. Assuming a linear relationship between pumping and water level, a 32 percent reduction in nearby pumping would lower pumping water levels by 68 percent of 81 feet (i.e., by 55 feet) in the Holy Cross Cemetery Well #4; and by 68 percent of 89 feet (i.e., by 61 feet) in the Hills of Eternity Cemetery Well. The pumping water levels in the Holy Cross Cemetery Well #4 and in the Hills of Eternity Cemetery Well at the end of the design drought are predicted to be below the top of the well screens. As a result, pumping groundwater levels at these wells is expected to fall below the top of the well screen under Alternative 3B; and the well interference impact on these wells would be *significant* under Alternative 3B, as it would be for the proposed Project.

Table 5.16-11 (Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought) also shows that, at the end of the design drought, the Project is predicted to lower pumping water levels in the Holy Cross Cemetery Well #1 by 86 feet. Assuming a linear relationship between pumping and water level, a 32 percent reduction in nearby pumping would lower pumping water levels by 68 percent of 86 feet (i.e., by 58 feet). The pumping water level in the Holy Cross Cemetery Well #1 at the end of the design drought is predicted to be slightly above the top of the well screen. Because pumping would not be redistributed to any other well sites under Alternative 3B, unlike Alternative 3A, no further reductions in water level would be expected. Furthermore, the pumping capacity of the Holy Cross Cemetery Well #1 is estimated to meet its peak demand when Project pumping is at a maximum, and a 32 percent reduction in nearby pumping, as per this alternative, would therefore not reduce the well's pumping capacity. As a result, the potential well interference impacts on the Holy Cross Cemetery well #1 would be *less than significant* under Alternative 3B, while the proposed Project impacts would be *significant*.

The Olivet Memorial Park well is expected to have just enough capacity to meet its expected demands, as predicted modeled existing conditions (see Impact H-6 in Section 5.16, Hydrology and Water Quality). Consequently, any lowering of groundwater levels at this well would likely result in this well having insufficient capacity to meet its expected demands. Therefore, even with the reduced pumping at Sites 7 and 8, the well interference impact on the Olivet Memorial Park well under Alternative 3B would be *significant*, as it would be for the proposed Project.

Table 5.16-11 (Estimated Static and Pumping Depth to Water Levels at the End of the Design Drought) also shows that, at the end of the design drought, the Project is predicted to lower pumping water levels in the Home of Peace Well by 81 feet. Under these Project conditions, this pumping water level would be below the top of the screen. Assuming a linear relationship between pumping and water level, a 32 percent reduction in nearby pumping would lower pumping water levels by 68 percent of 81 feet (i.e., by 55 feet). The pumping water level in the Home of Peace Well at the end of the design drought under Alternative 3B is predicted to be sufficiently above the top of the screen. Therefore, the reduced pumping at Sites 7 and 8 is expected to result in both pumping and static groundwater levels above the top of the well screen at the Home of Peace Cemetery Well at the end of the design drought. The pumping capacity of this well is estimated to meet its peak demand even when Project pumping would be at a maximum (Tables 5.16-13 [Estimated Peak Demand and 12-Hour Production Capacities]), and pumping capacity under Alternative 3B would be slightly greater as a result of eliminating pumping at Sites 7 and 8. As a result, the well interference impact on the Home of Peace Cemetery well would be *less than significant* under Alternative 3B, while the impact of the proposed Project on this well would be *significant* because the water levels due to Project pumping would be below the well screen, even though the pump discharge rate would be adequate to meet peak demand.

Under Alternative 3B, there would be no increase in pumping at other well sites, so potential well interference impacts under Alternative 3B at the San Francisco Golf Club, Olympic Club, and Lake Merced Golf Club would be essentially the same as for the proposed Project. The elimination of Sites 7 and 8 would not change the groundwater levels in the vicinity of these irrigation wells because they are too far from those GSR well sites to be affected by Sites 7 and 8. Therefore, the potential well interference impacts on the San Francisco Golf Club, Olympic Club, and Lake Merced Golf Club wells under Alternative 3B would be *less than significant*, as they would be for the proposed Project.

Land Subsidence. A 32 percent reduction in pumping near Colma would reduce the risk of subsidence in that area as compared to the Project. Therefore, potential subsidence impacts would be *less than significant* under Alternative 3B, as they would be for the proposed Project.

Seawater intrusion. Decreasing pumping in the Colma area by 32 percent would decrease the risk of seawater intrusion from the San Francisco Bay. Therefore, potential seawater intrusion impacts would be *less than significant* under Alternative 3B, as they would be for the proposed Project.

Adverse Effects on Beneficial Uses at Lake Merced. Pumping under Alternative 3B would not change near Lake Merced, as compared to the Project. Therefore, impacts on Lake Merced under Alternative 3B would be *less than significant with mitigation* relative to biological resources and to water quality, as they would be for the proposed Project. Mitigation Measures M-HY-9a (Lake Level Monitoring and Modeling for Lake Merced) and M-HY-9b (Lake Level Management for Lake Merced) would require the SFPUC to implement a lake level management program that includes monitoring to detect changes in lake levels, water quality, and groundwater, and the development and implementation of a strategy to augment lake levels or alter pumping to avoid adverse effects on Lake Merced. This mitigation measure would reduce the impacts of Alternative 3B to *less-than-significant* levels, as it would for the Project.

Water Quality Standards. A reduction in pumping in the Colma area would not affect the ability of the SFPUC to provide drinking water that meets drinking water quality standards, because the SFPUC would treat or blend groundwater as necessary to meet primary and secondary water quality standards and because the groundwater to be pumped is not considered vulnerable to soil or groundwater contamination due to the depth of pumping proposed. Therefore, the potential impact of Alternative 3B on drinking water quality would be *less than significant*, as it would be for the proposed Project.

Water Quality Degradation. Decreasing pumping in the Colma area would not affect water quality degradation from constituents not currently regulated because the existing concentration of such non-regulated constituents in the groundwater is lower than what would be likely to cause environmental harm, and decreased pumping would not increase or decrease these concentrations. Therefore, potential impacts of Alternative 3B relative to water quality degradation would be *less than significant*, as they would be for the proposed Project.

Groundwater Depletion. Because the overall yield from the Westside Groundwater Basin would be reduced to 6.0 mgd under this alternative, potential impacts on groundwater depletion would be less than those of the proposed Project and would remain *less than significant with mitigation*. Both the proposed Project and Alternative 3B would have the potential to result in depletion of the basin if losses from the SFPUC Storage Account were not considered in the management of pumping. With implementation of Mitigation Measure M-HY-14 (Prevent Groundwater Depletion), pumping would be managed to ensure that GSR wells would only be pumped when there is a positive balance in the SFPUC Storage Account, which would be adjusted for losses from the basin due to leakage.

Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield Conclusions

Alternative 3B would meet most, but not all, of the Project goals and objectives. It would provide for the conjunctive management of the South Westside Groundwater Basin, and it would provide supplemental SFPUC surface water to Partner Agencies in normal and wet years to allow for in-lieu recharge of the Basin. However, Alternative 3B would not fully meet the Project goal to provide 7.2 mgd of water for a new dry-year water supply for the SFPUC and Partner Agencies because Alternative 3B would reduce the number of wells and reduce the dry-year and emergency pumping capacity to 6.0 mgd.

The alternative would decrease pumping near Colma-area cemeteries by approximately 32 percent. This alternative would have the same construction-related impacts as the proposed Project except impacts associated with construction at Sites 7 and 8 would not occur. Operational impacts would be nearly the same as those expected for the proposed Project. This alternative would partially support the WSIP goals and objectives to provide dry-year and emergency water pumping capacity. However, additional measures may be necessary to fully provide the dry-year and emergency water pumping volume required in order to meet the WSIP goal of limiting rationing to a systemwide maximum of 20 percent during an 8.5 year drought.

Although this alternative would decrease pumping near the Colma-area by approximately 32 percent, the operational impacts would be similar to those expected for the proposed Project. The expected groundwater levels would still result in the potential for well interference impacts as would the proposed Project and these impacts, in most cases, are similar to those that would occur with the proposed Project. Alternative 3B would reduce the potential for subsidence and seawater intrusion; however, both the proposed Project and Alternative 3B would result in less than significant impacts. Potential impacts on groundwater quality would be the same for the proposed Project and the alternative. Potential impacts related to groundwater depletion would be similar for both the Project and this alternative.

7.4 COMPARISON OF ALTERNATIVES

Table 7.2 (Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project) provides a comparison of the environmental impacts of the alternatives as compared to the impacts of the proposed Project. The table does not include those impact categories for which the proposed Project would result in No Impact or a Less than Significant Impact at all sites. A comparison of the alternatives follows the table along with a discussion of the environmentally superior alternative.

TABLE 7-2
Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project

Impact	Proposed Project	Alternative 1: No Project	Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield	Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield	Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield	Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield
Land Use						
Impact LU-1. Project construction would have a substantial impact on the existing character of the vicinity and could substantially disrupt or displace existing land uses or land use activities.	**Significant and Unavoidable with Mitigation (SUM)** Construction-related noise, traffic, air quality and recreation impacts could temporarily substantially disrupt or displace existing land uses. Mitigation Measures M-NO-1, M-NO-3, M-LU-1a, AQ-2a, AQ-3, and M-TR-1 would reduce impacts to less-than-significant levels at some sites; however the impact would remain SUM at 10 sites.	**Same as existing condition (NI)** There would be no construction activities, and therefore no land use impacts.	**Similar to but less than the proposed Project (SUM)** Under the Project, Sites 1 and 4 contribute to the significant impact. With removal of these well facilities, construction impacts to land use would be slightly less than the proposed Project, however, eight sites would continue to have significant and unavoidable impacts.	**Similar to but less than the proposed Project (SUM)** Under the Project, Sites 1 and 4 contribute to the significant impact. With removal of these well facilities, construction impacts to land use would be slightly less than the proposed Project, however, eight sites would continue to have significant and unavoidable impacts.	**Similar to but slightly less than the proposed Project (SUM)** Under the Project, Site 7 contributes to the significant impact though the impact would be mitigable. Omission of Site 7 would slightly reduce overall land use impacts, although 10 sites would continue to have significant and unavoidable impacts.	**Similar to but slightly less than the proposed Project (SUM)** Under the Project, Site 7 contributes to the significant impact though the impact would be mitigable. Omission of Site 7 would slightly reduce overall land use impacts, although 10 sites would continue to have significant and unavoidable impacts.
Impact LU-2. Project operations would result in substantial long-term or permanent impacts on the existing character or disrupt or displace land uses.	**Less than Significant with Mitigation (LSM)** Nighttime noise from operations could potentially disrupt land uses at five sites. Mitigation Measure M-NO-5 would reduce the impact to a less-than-significant level.	**Same as existing condition (NI)** There would be no changes to existing operations at the Westlake Pump Station, and no new GSR well facilities would be constructed.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Site 1 would have a mitigable impact on its surrounding land use. This alternative would reduce the land use impact slightly by eliminating Site 4 where impacts are LSM. Impacts at four sites would remain LSM.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Site 1 would have a mitigable impact on its surrounding land use. This alternative would reduce the land use impact slightly by eliminating Site 1 where impacts are LSM. Impacts at four sites would remain LSM.	**Same as the proposed Project (LSM)** Under the Project, Sites 7 and 8 do not contribute to the significant impact, so the omission of these well facilities would not change the significance of this impact.	**Same as the proposed Project (LSM)** Under the Project, Sites 7 and 8 do not contribute to the significant impact, so the omission of these well facilities would not change the significance of this impact.
Impact C-LU-1. Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to land use.	**Significant and Unavoidable with Mitigation (SUM)** Construction could result in a cumulatively considerable contribution to cumulative land use impacts at Sites 9, 12, and 19. Even with implementation of Mitigation Measures M-NO-1 and M-NO-3, the impact could remain SUM.	**Same as existing condition (NI)** There would be no construction activities. No new GSR well facilities would be constructed so no noise caused land use impacts would be generated.	**Same as the proposed Project (SUM)** Under the Project, Sites 1 and 4 do not contribute to the significant impact, so the omission of these well facilities would not change the significance of this impact.	**Same as the proposed Project (SUM)** Under the Project, Sites 1 and 4 do not contribute to the significant impact, so the omission of these well facilities would not change the significance of this impact.	**Same as the proposed Project (SUM)** Under the Project, Sites 7 (On-site) and Site 8 do not contribute to the significant impact, so the omission of these well facilities would not change the significance of this impact.	**Same as the proposed Project (SUM)** Under the Project, Sites 7 (On-site) and Site 8 do not contribute to the significant impact, so the omission of these well facilities would not change the significance of this impact.

TABLE 7-2
Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project

Impact	Proposed Project	Alternative 1: No Project	Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield	Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield	Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield	Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield
Aesthetics						
Impact AE-1. Project construction would have a substantial adverse impact on a scenic vista, resource, or on the visual character of a site or its surroundings.	**Significant and Unavoidable with Mitigation (SUM)** Project construction at seven sites would be visible from areas with moderate to high visual sensitivity and significant viewer concern, and construction of Site 15 would be visible from a locally designated scenic route, which would be a significant impact. Mitigation Measures M-AE-1a, M-AE-1b, M-AE-1c, M-AE-1d, M-AE-1e, and M-CR-1a would reduce the impact at most sites; however, construction would result in a significant and unavoidable impact at Site 7, even with the implementation of the mitigations.	**Same as existing condition (NI)** There would be no construction activities; and therefore no visual impacts.	**Similar to but slightly less than the proposed Project (SUM)** Under the Project, Site 4 contributes to the significant impact. Omission of this site would reduce construction-related aesthetic impacts at residences, Ben Franklin Intermediate School athletic field and Garden Village Elementary School. However, visual impacts would still occur at seven other sites, and a significant and unavoidable impact would remain at Site 7.	**Similar to but slightly less than the proposed Project (SUM)** Under the Project, Site 4 contributes to the significant impact. Omission of the site would reduce construction-related aesthetic impacts at residences, Ben Franklin Intermediate School athletic field and Garden Village Elementary School. However, visual impacts would still occur at seven sites, and a significant and unavoidable impact would remain at Site 7.	**Similar to but less than the proposed Project (LSM)** Under the Project, Site 7 (under both Consolidated Treatment at Site 6 and On-Site Treatment) contributes to the significant impact. Omission of this site would reduce aesthetic impacts at several cemeteries, the Colma Bay Area Rapid Transit (BART) Station and Metro Shopping Center. Visual impacts would still occur at six sites, but impacts can be reduced to less-than-significant levels.	**Similar to but less than the proposed Project (LSM)** Under the Project, Site 7 (Consolidated and On-Site) contributes to the significant impact. Omission of this site would reduce aesthetic impacts at several cemeteries, the Colma BART Station and Metro Shopping Center. Visual impacts would still occur at six sites, but impacts can be reduced to less-than-significant levels.
Impact AE-3. Project operation would have a substantial adverse impact on a scenic vista, resource, or on the visual character of a site or its surroundings.	**Less than Significant with Mitigation (LSM)** Project facilities would be visible and may have an adverse impact on the visual character at five sites. Mitigation Measures M-AE-3a, M-CR-5a, and M-CR-5b would reduce impacts.	**Same as existing conditions (NI)** No new GSR well facilities would be constructed, and therefore no visual impacts would occur.	**Same as the proposed Project Less than Significant with Mitigation (LSM)** Under the Project, Site 4 contributes to the significant impact. Omission of the site under this alternative would reduce the impact; however, impacts on the visual character of the surrounding areas would remain at four other sites.	**Same as the proposed Project Less than Significant with Mitigation (LSM)** Under the Project, Site 4 contributes to the significant impact. Omission of the site under this alternative would reduce the impact; however, impacts on the visual character of the surrounding areas would remain at four other sites.	**Similar to but less than the proposed Project (LSM)** Under the Project, Site 7 contributes to the significant impact. Omission of Site 7 would eliminate the visual impact at the site. Significant, but mitigable impacts would remain at four sites.	**Similar to but less than the proposed Project (LSM)** Under the Project, Site 7 contributes to the significant impact. Omission of Site 7 would eliminate the visual impact at the site. Significant, but mitigable impacts would remain at foursites.

TABLE 7-2
Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project

Impact	Proposed Project	Alternative 1: No Project	Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield	Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield	Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield	Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield
Impact C-AE-1. Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to scenic resources and visual character.	**Less than Significant with Mitigation (LSM)** Project construction and operations in addition to other projects may result in a cumulative impact to visual character of the area at Sites 12 and 13 Mitigation Measure M-AE-1a, M-AE-1b, and M-AE-3a would reduce impacts to less-than-significant levels.	**Same as the existing conditions (NI)** No new GSR well facilities would be constructed, and therefore there would be no cumulative visual impacts.	**Same as the proposed Project (LSM)** Sites, 12 and13 would have a cumulatively considerable contribution to cumulative impacts on the visual character of the surrounding area. This alternative includes facilities at these sites.	**Same as the proposed Project (LSM)** Sites, 12 and 13 would have a cumulatively considerable contribution to cumulative impacts on the visual character of the surrounding area. This alternative includes facilities at these sites.	**Similar to but slightly less than the proposed Project (LSM)** Sites 12 and 13 would have a cumulatively considerable contribution to cumulative impacts on the visual character of the surrounding area. The alternative would not reduce the impact.	**Similar to but slightly less than the proposed Project (LSM)** Sites 12 and 13 would have a cumulatively considerable contribution to cumulative impacts on the visual character of the surrounding area. The alternative would not reduce the impact.
Cultural and Paleontological Resources						
Impact CR-1. Project construction could cause an adverse change in the significance of a historical resource.	**Less than Significant with Mitigation (LSM)** Construction of the Project could affect the significance of historical resources at Sites 14 and 15. Mitigation measures M-CR-1a, M-CR-1b, and M-NO-2 would reduce the potential impacts to less-than-significant levels.	**Same as the existing conditions (NI)** No new GSR well facilities would be constructed, and therefore, there would be impacts on historical resources.	**Same as the proposed Project (LSM)** Construction of well facilities at Sites 14 and 15 would be included as part of this alternative; therefore the impacts would be the same as the proposed Project.	**Same as the proposed Project (LSM)** Construction of well facilities at Sites 14 and 15 would be included as part of this alternative; therefore the impacts would be the same as the proposed Project.	**Same as the proposed Project (LSM)** Construction of well facilities at Sites 14 and 15 would be included as part of this alternative; therefore the impacts would be the same as the proposed Project.	**Same as the proposed Project (LSM)** Construction of well facilities at Sites 14 and 15 would be included as part of this alternative; therefore the impacts would be the same as the proposed Project.
Impact CR-2. Project construction could cause an adverse change in the significance of an archaeological resource.	**Less than Significant with Mitigation (LSM)** Construction of the Project could affect a previously undiscovered archaeological resource at all sites, except for the Westlake Pump Station. Mitigation Measure M-CR-2 would reduce impacts to less-than-significant levels.	**Same as the existing conditions (NI)** There would be no construction activities, and therefore no impacts on cultural resources.	**Similar to but slightly less than the proposed Project (LSM)** Because this alternative would involve less ground disturbance, the potential to adversely affect archaeological resources would be slightly decreased by eliminating Sites 1 and 4.	**Similar to but slightly less than the proposed Project (LSM)** Because this alternative would involve less ground disturbance, the potential to adversely affect archaeological resources would be slightly decreased by eliminating Sites 1 and 4.	**Similar to but slightly less than the proposed Project (LSM)** Because this alternative would involve less ground disturbance, the potential to adversely affect archaeological resources would be slightly decreased by eliminating Sites 7 and 8.	**Similar to but slightly less than the proposed Project (LSM)** Because this alternative would involve less ground disturbance, the potential to adversely affect archaeological resources would be slightly decreased by eliminating Sites 7 and 8.

TABLE 7-2
Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project

Impact	Proposed Project	Alternative 1: No Project	Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield	Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield	Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield	Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield
Impact CR-3. Project construction could result in a substantial adverse effect by destroying a unique paleontological resource or site.	**Less than Significant with Mitigation (LSM)** Construction could destroy a paleontological resource except at the Westlake Pump Station and Site 9. Mitigation Measure M-CR-3 would reduce the impacts to less-than-significant levels.	**Same as the existing conditions (NI)** There would be no construction activities, and therefore there would be no impacts on unique paleontological resources.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant impact because they are located on surface deposits considered to have a high paleontological sensitivity for significant paleontological resources. Therefore, without these two sites, the potential for adverse effects related to unique paleontological resources is slightly decreased.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant impact because they are located on surface deposits considered to have a high paleontological sensitivity for significant paleontological resources. Therefore, without these two sites, the potential for adverse effects related to unique paleontological resources is slightly decreased.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant impact because they are located on surface deposits considered to have a high paleontological sensitivity for significant paleontological resources. Therefore, without these two sites, the potential for adverse effects related to unique paleontological resources is slightly decreased.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant impact because they are located on surface deposits considered to have a high paleontological sensitivity for significant paleontological resources. Therefore, without these two sites, the potential for adverse effects related to unique paleontological resources is slightly decreased.
Impact CR-4. Project construction could result in a substantial adverse effect related to the disturbance of human remains.	**Less than Significant with Mitigation (LSM)** Construction could result in an impact on human remains at all sites except for the Westlake Pump Station. Mitigation Measure M-CR-4 would reduce the impacts to less-than-significant levels for all sites.	**Same as the existing conditions (NI)** There would be no construction activities. No impacts on human remains would occur.	**Similar to but slightly less than the proposed Project (LSM)** Because this alternative would involve less ground disturbance, the potential to encounter human remains would be slightly decreased by eliminating Sites 1 and 4.	**Similar to but slightly less than the proposed Project (LSM)** Because this alternative would involve less ground disturbance, the potential to encounter human remains would be slightly decreased by eliminating Sites 1 and 4.	**Similar to but slightly less than the proposed Project (LSM)** Because this alternative would involve less ground disturbance, the potential to encounter human remains would be slightly decreased by eliminating Sites 7 and 8.	**Similar to but slightly less than the proposed Project (LSM)** Because this alternative would involve less ground disturbance, the potential to encounter human remains would be slightly decreased by eliminating Sites 7 and 8.
Impact CR-5. Project facilities could cause an adverse change in the significance of a historical resource.	**Less than Significant with Mitigation (LSM)** Construction of the Project facilities could result in an impact on the historical resources at or near Sites 14 and 15 in the Golden Gate National Cemetery. Mitigation Measures M-CR-5a and M-CR-5b would reduce the impacts to less-than-significant levels for both well facility sites.	**Same as the existing conditions (NI)** There would be no construction activities, and therefore no impacts on historical resources would occur.	**Same as the proposed Project (LSM)** Construction of the Project facilities at Sites 14 and 15 would occur under this alternative, and therefore the potential impacts on historical resources are the same as the proposed Project.	**Same as the proposed Project (LSM)** Construction of the Project facilities at Sites 14 and 15 would occur under this alternative, and therefore the potential impacts on historical resources are the same as the proposed Project.	**Same as the proposed Project (LSM)** Construction of the Project facilities at Sites 14 and 15 would occur under this alternative, and therefore the potential impacts on historical resources are the same as the proposed Project.	**Same as the proposed Project (LSM)** Construction of the Project facilities at Sites 14 and 15 would occur under this alternative, and therefore the potential impacts on historical resources are the same as the proposed Project.

TABLE 7-2
Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project

Impact	Proposed Project	Alternative 1: No Project	Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield	Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield	Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield	Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield
Impact C-CR-1. Construction of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts on historical, archaeological, or paleontological resources, or human remains.	**Less than Significant with Mitigation (LSM)** Construction could result in a cumulatively considerable contribution to cumulative impacts except at the Westlake Pump Station. Mitigation Measures M-CR-2, M-CR-3 and M-CR-4 would reduce impacts to less than significant levels.	**Same as existing conditions (NI)** There would be no construction activities, and no cumulative impacts on cultural, historical, or paleontological resources would occur.	**Similar to but slightly less than the proposed Project (LSM)** Under this alternative, cumulative impacts on paleontological resources, archaeological resources or human remains would be slightly reduced because there would be no ground disturbance in the locations of Sites 1 and 4.	**Similar to but slightly less than the proposed Project (LSM)** Under this alternative, cumulative impacts on paleontological resources, archaeological resources or human remains would be slightly reduced because there would be no ground disturbance in the locations of Sites 1 and 4.	**Similar to but slightly less than the proposed Project (LSM)** Under this alternative, cumulative impacts on paleontological resources, archaeological resources or human remains would be slightly reduced because there would be no ground disturbance in the locations of Sites 7 and 8.	**Similar to but slightly less than the proposed Project (LSM)** Under this alternative, cumulative impacts on paleontological resources, archaeological resources or human remains would be slightly reduced because there would be no ground disturbance in the locations of Sites 7 and 8.
Transportation and Circulation						
Impact TR-1. The Project would conflict with an applicable plan, ordinance or policy establishing measures of effectiveness for the performance of the circulation system.	**Less than Significant with Mitigation (LSM)** Construction traffic could affect the performance of the circulation system at 12 sites. Mitigation Measure M-TR-1 would reduce the impacts to less-than-significant levels.	**Same as existing conditions (NI)** There would be no construction activities and no impacts on the performance of the circulation system would occur.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Site 1 would not contribute to the significant impact related to travel lane closures. In this alternative, impacts to Park Plaza Drive would be slightly reduced by elimination of Site 4. A less-than-significant impact would remain at 11 sites.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Site 1 would not contribute to the significant impact related to travel lane closures. In this alternative, impacts to Park Plaza Drive would be slightly reduced by elimination of Site 4. A less-than-significant impact would remain at 11 sites.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Site 7 contributes to the significant impact related to travel lane closures. In this alternative, impacts to Colma Blvd. would be eliminated; therefore the impact would be slightly reduced. A less-than-significant impact would remain at 11 sites.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Site 7 contributes to the significant impact related to travel lane closures. In this alternative, impacts to Colma Blvd. would be eliminated; therefore the impact would be slightly reduced. A less-than-significant impact would remain at 11 sites.
Impact TR-2. The Project would temporarily impair emergency access to adjacent roadways and land uses during construction.	**Less than Significant with Mitigation (LSM)** Temporary impacts on emergency access could occur during construction at three sites. Mitigation Measure M-TR-1 would reduce impacts to less-than-significant levels.	**Same as existing conditions (NI)** There would be no construction activities and no temporary access impacts would occur.	**Same as the proposed Project (LSM)** Under the Project, Sites 1 and 4 would not contribute to the significant impact; therefore the impacts would the same as the proposed Project.	**Same as the proposed Project (LSM)** Under the Project, Sites 1 and 4 would not contribute to the significant impact; therefore the impacts would be the same as the proposed Project.	**Same as the proposed Project (LSM)** Under the Project, Sites 7 and 8 do not contribute to the significant impact, so the omission of these well facilities would not change the significance of this impact.	**Same as the proposed Project (LSM)** Under the Project, Sites 7 and 8 do not contribute to the significant impact, so the omission of these well facilities would not change the significance of this impact.
Impact TR-3. The Project would temporarily decrease the performance and safety of public transit, bicycle, and pedestrian facilities during construction.	**Less than Significant with Mitigation (LSM)** Project construction could temporarily impact the performance and safety of bicycle, pedestrian, and public transit systems during construction at five sites. Mitigation Measure M-TR-1 would reduce impacts to less-than-significant levels.	**Same as existing conditions (NI)** There would be no construction activities, and therefore no transit systems would be affected.	**Same as the proposed Project (LSM)** Under the Project, Sites 1 and 4 would not contribute to the significant impact on transit systems; therefore the impacts would be the same as the proposed Project.	**Same as the proposed Project (LSM)** Under the Project, Sites 1 and 4 would not contribute to the significant impact on transit systems; therefore the impacts would be the same as the proposed Project.	**Same as the proposed Project (LSM)** Under the Project, Sites 7 and 8 do not contribute to the significant impact, so the omission of these well facilities would not change the significance of this impact.	**Same as the proposed Project (LSM)** Under the Project, Sites 7 and 8 do not contribute to the significant impact, so the omission of these well facilities would not change the significance of this impact.

TABLE 7-2
Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project

Impact	Proposed Project	Alternative 1: No Project	Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield	Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield	Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield	Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield
Impact C-TR-1. Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to transportation and circulation.	**Less than Significant with Mitigation (LSM)** The Project could result in a cumulatively considerable contribution to impaired emergency access and create traffic hazards for alternative modes of transportation at 13 sites. Mitigation Measures M-TR-1 and M-C-TR-1 would reduce impacts to less-than-significant levels.	**Same as existing conditions (NI)** There would be no construction activities. No new GSR well facilities would be constructed and, therefore, no related traffic impacts would result.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Site 4 contributes to the cumulative significant impact related to impairing emergency access and the safety of pedestrians and bicyclists. In this alternative, impacts related to pedestrian, bicycle and emergency access to Park Plaza Drive would be eliminated, and therefore the impact would be slightly less than the proposed Project.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Site 4 contributes to the cumulative significant impact related to impairing emergency access and the safety of pedestrians. Under this alternative, impacts related to pedestrian, bicycle and emergency access to Park Plaza Drive would be eliminated, and therefore the impact would be slightly less than the proposed Project.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Site 7 contributes to the cumulative significant impact related to impairing emergency access and the safety of pedestrians and bicyclists; however, Site 8 does not contribute to the significant impact. Therefore, the elimination of Site 7 would reduce the impact slightly.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Site 7 contributes to the cumulative significant impact related to impairing emergency access and the safety of pedestrians and bicyclists; however, Site 8 does not contribute to the significant impact. Therefore, the elimination of Site 7 would reduce the impact slightly.
Noise and Vibration						
Impact NO-1. Project construction would result in noise levels in excess of local standards.	**Significant and Unavoidable with Mitigation (SUM)** Project construction would result in noise levels that exceed local noise standards at 14 sites. Mitigation Measure M-NO-1 would reduce this impact at seven of the sites, but the impact would remain significant at the other sites. At Sites 1, 4, 9, 12, 16, 18 (Alternate), and 19 (Alternate), there is no mitigation to avoid nighttime drilling, which is not allowed in the relevant jurisdictions, so the impact is significant and unavoidable at those sites.	**Same as existing conditions (NI)** There would be no construction activities, and no related noise impacts would occur.	**Similar to but slightly less than the proposed Project (SUM)** Under the Project, Sites 1 and 4 contribute to the significant and unavoidable impact. Under this alternative, significant and unavoidable noise impacts would be reduced because of the omission of facilities at these sites; however the significant and unavoidable impact would still occur at five sites.	**Similar to but slightly less than the proposed Project (SUM)** Under the Project, Sites 1 and 4 contribute to the significant and unavoidable impact. Under this alternative, significant and unavoidable noise impacts would be reduced because of the omission of facilities at these sites; however the significant and unavoidable impact would still occur at five sites.	**Same as the proposed Project (SUM)** Under the Project, Sites 7 and 8 do not contribute to the significant and unavoidable impact, so the omission of these well facilities would not change the significance of this impact.	**Same as the proposed Project (SUM)** Under the Project, Sites 7 and 8 do not contribute to the significant and unavoidable impact, so the omission of these well facilities would not change the significance of this impact.

TABLE 7-2
Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project

Impact	Proposed Project	Alternative 1: No Project	Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield	Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield	Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield	Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield
Impact NO-2. Project construction would result in excessive groundborne vibration.	**Less than Significant with Mitigation (LSM)** Project construction could result in excessive groundborne vibration at five sites. Mitigation Measures M-NO-2 would reduce this impact to less-than significant levels.	**Same as existing conditions (NI)** There would be no construction activities so groundborne vibration would not occur.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Site 4 contributes to the significant impact. Under this alternative, groundborne vibration impacts would be slightly reduced due to the omission of Site 4. However, excessive groundborne vibration would still occur at four sites.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Site 4 contributes to the significant impact. Under this alternative, groundborne vibration impacts would be slightly reduced due to the omission of Site 4. However, excessive groundborne vibration would still occur at four sites.	**Same as the proposed Project (LSM)** Under the Project, Sites 7 and 8 do not contribute to the significant impact, so the omission of these well facilities would not change the significance of this impact.	**Same as the proposed Project (LSM)** Under the Project, Sites 7 and 8 do not contribute to the significant impact, so the omission of these well facilities would not change the significance of this impact.
Impact NO-3. Project construction would result in a substantial temporary increase in ambient noise levels.	**Significant and Unavoidable with Mitigation (SUM)** Project construction would result in a substantial temporary increase in ambient noise levels at 15 sites, ten of which would have significant and unavoidable impacts. Mitigation Measures M-NO-1 and M-NO-3 would reduce this impact, but the impact would remain significant.	**Same as existing conditions (NI)** There would be no construction activities and no related temporary increases in ambient noise levels would occur.	**Similar to but slightly less than the proposed Project (SUM)** Under the Project, Sites 1 and 4 contribute to the significant and unavoidable impact. Under this alternative, the number of sites with significant and unavoidable impacts would be reduced to eight because of the omission of Sites 1 and 4.	**Similar to but slightly less than the proposed Project (SUM)** Under the Project, Sites 1 and 4 contribute to the significant and unavoidable impact. Under this alternative, the number of sites with significant and unavoidable impacts would be reduced to eight because of the omission of Sites 1 and 4.	**Similar to but slightly less than the proposed Project (SUM)** Under the Project, Sites 7 and 8 do not contribute to the significant and unavoidable impact. Under this alternative, significant and unavoidable impacts would remain at 10 sites.	**Similar to but slightly less than the proposed Project (SUM)** Under the Project, Sites 7 and 8 do not contribute to the significant and unavoidable impact. Under this alternative, significant and unavoidable impacts would remain at 10 sites.
Impact NO-5. Operation of the Project would result in exposure of people to noise levels in excess of local noise standards or result in a substantial permanent increase in ambient noise levels in the Project vicinity.	**Less than Significant with Mitigation (LSM)** Project operations would result in exposure of persons to, or generation of, noise levels in excess of standards established in the local general plan or noise ordinance at seven sites. Mitigation Measure M-NO-5 would reduce this impact to less-than significant levels.	**Same as existing conditions (NI)** No new GSR well facilities would be constructed, so no related noise would be generated.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Site 1 contributes to the significant impact. Under this alternative, operational noise impacts would be slightly reduced because of the omission of this site. Noise impacts would occur at six sites.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Site 1 contributes to the significant impact. Under this alternative, operational noise impacts would be slightly reduced because of the omission of this site. Noise impacts would occur at six sites.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Site 7 (On-site Treatment) contributes to the significant impact. Under this alternative, operational noise impacts would be slightly reduced because of the omission of this site. Noise impacts would occur at six sites.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Site 7 (On-site Treatment) contributes to the significant impact. Under this alternative, operational noise impacts would be slightly reduced because of the omission of this site. Noise impacts would occur at six sites.

TABLE 7-2
Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project

Impact	Proposed Project	Alternative 1: No Project	Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield	Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield	Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield	Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield
Impact C-NO-1. Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to noise.	**Significant and Unavoidable with Mitigation (SUM)** The Project could result in a cumulatively considerable contribution to cumulative impacts related to construction noise at Sites 12 and 19 (Alternate) even with the implementation of Mitigation Measures M-NO-1, M-NO-3, and M-NO-5.	**Same as existing conditions (NI)** There would be no construction activities. No new GSR well facilities would be constructed, so no related noise would be generated.	**Same as the proposed Project (SUM)** Under the Project, Sites 1 and 4 do not contribute to the significant and unavoidable impact, so the omission of these well facilities would not change the significance of this impact.	**Same as the proposed Project (SUM)** Under the Project, Sites 1 and 4 do not contribute to the significant and unavoidable impact, so the omission of these well facilities would not change the significance of this impact.	**Similar to but slightly less than the proposed Project (SUM)** Under the Project, Sites 7 (On-site Treatment) and 8 contribute to the significant cumulative impact. Under this alternative, cumulative construction noise impacts would be slightly reduced because of the omission of these two sites.	**Similar to but slightly less than the proposed Project (SUM)** Under the Project, Sites 7 (On-site Treatment) and 8 contribute to the significant cumulative impact. Under this alternative, cumulative construction noise impacts would be slightly reduced because of the omission of these two sites.
Air Quality						
Impact AQ-2: Emissions generated during construction activities would violate air quality standards and would contribute substantially to an existing air quality violation.	**Less than Significant with Mitigations (LSM)** Construction of the Project may result in violations of air quality standards and contribute substantially to existing air quality violations at all sites. Mitigation Measures M-AQ-2a and M-AQ-2b would reduce impacts at all sites to less-than-significant levels.	**Same as existing conditions (NI)** There would be no construction activities. Related construction emissions would therefore not occur.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant impact. Under this alternative, air quality impacts would be slightly reduced because of the overall decrease in construction. Emissions would occur at 14 sites and at the Westlake Pump Station.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant impact. Under this alternative, air quality impacts would be slightly reduced because of the overall decrease in construction. Emissions would occur at 14 sites and at the Westlake Pump Station.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant impact. Under this alternative, air quality impacts would be slightly reduced because of the overall decrease in construction. Emissions would occur at 14 sites and at the Westlake Pump Station.	**Similar to but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant impact. Under this alternative, air quality impacts would be slightly reduced because of the overall decrease in construction. Emissions would occur at 14 sites and at the Westlake Pump Station.
Impact AQ-3: Project construction would expose sensitive receptors to substantial pollutant concentrations.	**Less than Significant with Mitigations (LSM)** Project construction would expose sensitive receptors to pollutant concentrations at Site 5. Mitigation Measure M-AQ-3 would reduce impacts to less-than-significant levels.	**Same as existing conditions (NI)** There would be no construction activities. Sensitive receptors would not be exposed to related pollutant concentrations.	**Same as the proposed Project (LSM)** This alternative includes construction at Site 5; therefore the impact would be the same as the proposed Project.	**Same as the proposed Project (LSM)** This alternative includes construction at Site 5; therefore the impact would be the same as the proposed Project.	**Same as the proposed Project (LSM)** This alternative includes construction at Site 5; therefore the impact would be the same as the proposed Project.	**Same as the proposed Project (LSM)** This alternative includes construction at Site 5; therefore the impact would be the same as the proposed Project.
Impact C-AQ-1: Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to air quality.	**Less than Significant with Mitigation (LSM)** Project construction could result in a cumulatively considerable contribution to cumulative impacts related to air quality at all sites. Mitigation Measure M-AQ-2b would reduce impacts to less-than significant levels.	**Same as existing conditions (NI)** There would be no construction activities. Cumulative air quality impacts would not occur.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant impact. Under this alternative, air quality impacts would be slightly reduced because of the overall decrease in construction.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant impact. Under this alternative, air quality impacts would be slightly reduced because of the overall decrease in construction.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant impact. Under this alternative, air quality impacts would be slightly reduced because of the overall decrease in construction.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant impact. Under this alternative, air quality impacts would be slightly reduced because of the overall decrease in construction.

TABLE 7-2
Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project

Impact	Proposed Project	Alternative 1: No Project	Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield	Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield	Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield	Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield
Recreation						
Impact RE-2. The Project would deteriorate the quality of the recreational experience during construction.	**Less than Significant with Mitigation (LSM)** The Project would deteriorate the quality of the recreational experience during construction at Sites 1, 2, and 4. Mitigation Measure M-AQ-2a would reduce the impact at this site.	**Same as existing conditions (NI)** There would be no construction activities, and impacts to recreational resources would not occur.	**Similar but less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant impact. Under this alternative, because Sites 1 and 4 are omitted, the less-than-significant-with-mitigation impact is only associated with construction at Site 2.	**Similar but less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant impact. In this alternative, because Sites 1 and 4 are omitted, the less-than-significant-with-mitigation impact is only associated with construction at Site 2.	**Same as the proposed Project (LSM)** Under the Project, Sites 7 and 8 do not contribute to the significant impact, so the omission of these well facilities would not change the significance of this impact.	**Same as the proposed Project (LSM)** Under the Project, Sites 7 and 8 do not contribute to the significant impact, so the omission of these well facilities would not change the significance of this impact.
Utilities and Service Systems						
Impact UT-1. Project construction could result in potential damage to or temporary disruption of existing utilities during construction.	**Less than Significant with Mitigation (LSM)** Construction of the Project could result in damage to or disruption of existing utilities at all sites. Mitigation Measures M-UT-1a through M-UT-1i would reduce impacts to less-than-significant levels.	**Same as existing conditions (NI)** There would be no construction activities and utility service would not be temporarily disrupted.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant impact. Under this alternative, impacts on existing utilities impacts would be slightly reduced because of the overall decrease in construction. Utility impacts could occur at 17 sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant impact. Under this alternative, impacts on existing utilities impacts would be slightly reduced because of the overall decrease in construction. Utility impacts could occur at 17 sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant impact. Under this alternative, impacts on existing utilities impacts would be slightly reduced because of the overall decrease in construction. Utility impacts could occur at 17 sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant impact. Under this alternative, impacts on existing utilities impacts would be slightly reduced because of the overall decrease in construction. Utility impacts could occur at 17 sites.
Impact UT-4. Project construction could result in a substantial adverse effect related to compliance with federal, State, and local statutes and regulations pertaining to solid waste.	**Less than Significant with Mitigation (LSM)** Project construction may not comply with federal, State, and local (Daly City, Colma, South San Francisco, San Bruno, Millbrae and San Mateo County) regulations pertaining to solid waste disposal at all sites. Mitigation Measure M-UT-4 would reduce impacts at all sites.	**Same as existing conditions (NI)** There would be no construction activities.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant impact. Under this alternative, impacts related to solid waste would be slightly reduced because of the overall decrease in construction. However, other sites would still need to comply with the applicable waste management ordinance.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant impact. Under this alternative, impacts related to solid waste would be slightly reduced because of the overall decrease in construction. However, other sites would still need to comply with the applicable waste management ordinance.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant impact. Under this alternative, impacts related to solid waste would be slightly reduced because of the overall decrease in construction. However, other sites would still need to comply with the applicable waste management ordinance.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant impact. Under this alternative, impacts related to solid waste would be slightly reduced because of the overall decrease in construction. However, other sites would still need to comply with the applicable waste management ordinance.

TABLE 7-2
Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project

Impact	Proposed Project	Alternative 1: No Project	Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield	Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield	Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield	Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield
Impact C-UT-1. Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to utilities and service systems.	**Less than Significant with Mitigation (LSM)** The Project could result in a cumulatively considerable contribution to cumulative impacts related to utilities and service systems at all sites. Mitigation Measures M-UT-1a through M-UT-1i and M-UT-4 would reduce impacts to less-than significant levels.	**Same as existing conditions (NI)** There would be no construction activities and, therefore, no related impacts on utilities.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant cumulative impact. Under this alternative, impacts related to existing utilities and solid waste would be slightly reduced because of the overall decrease in construction. However, other sites would still have the potential to contribute to cumulative impacts on existing utilities and solid waste disposal.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant cumulative impact. Under this alternative, impacts related to existing utilities and solid waste would be slightly reduced because of the overall decrease in construction. However, other sites would still have the potential to contribute to cumulative impacts on existing utilities and solid waste disposal.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant cumulative impact. Under this alternative, impacts related to existing utilities and solid waste would be slightly reduced because of the overall decrease in construction. However, other sites would still have the potential to contribute to cumulative impacts on existing utilities and solid waste disposal.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant cumulative impact. Under this alternative, impacts related to existing utilities and solid waste would be slightly reduced because of the overall decrease in construction. However, other sites would still have the potential to contribute to cumulative impacts on existing utilities and solid waste disposal.
Biological Resources						
Impact BR-1. Project construction would adversely affect candidate, sensitive, or special-status species.	**Less than Significant with Mitigation (LSM)** Project construction could adversely impact special-status species at all sites. Mitigation Measures M-BR-1a through M-BR-1d would reduce impacts to less-than–significant levels.	**Same as existing conditions (NI)** There would be no construction or operational activities and, therefore, no related construction or operational impacts on specials-status species.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant impact related to birds and bats. Site 1 contributes to significant impacts related to overwintering monarch butterfly habitat. Under this alternative, these impacts would be slightly reduced because of the omission of these sites. However, significant impacts on these special-status species could still occur at other sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant impact related to birds and bats. Site 1 contributes to significant impacts related to overwintering monarch butterfly habitat. Under this alternative, these impacts would be slightly reduced because of the omission of these sites. However, significant impacts on these special-status species could still occur at other sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant impact related to birds. Site 7 contributes to significant impacts related to bats and overwintering monarch butterfly habitat. Under this alternative, these impacts would be slightly reduced because of the omission of these sites. However, significant impacts on these special-status species could still occur at other sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant impact related to birds. Site 7 contributes to significant impacts related to bats and overwintering monarch butterfly habitat. Under this alternative, these impacts would be slightly reduced because of the omission of these sites. However, significant impacts on these special-status species could still occur at other sites.
Impact BR-2. Project construction could adversely affect riparian habitat or other sensitive natural communities.	**Less than Significant with Mitigation (LSM)** Project construction at Site 1 could adversely affect Central Coast riparian scrub habitat. Mitigation Measures M-BR-2 and M-HY-1 would reduce impacts at Site 1 to less-than–significant levels.	**Same as existing conditions (NI)** There would be no construction activities, and no sensitive natural communities would be affected as a result.	**Less than the proposed Project (NI)** Construction would not occur at Site 1; therefore there would be no impacts on riparian habitat or other sensitive natural communities at that site under this alternative.	**Less than the proposed Project (NI)** Construction would not occur at Site 1; therefore there would be no impacts on riparian habitat or other sensitive natural communities at that site under this alternative.	**Same as the proposed Project (LSM)** Sites 7 and 8 do not contribute to the significant impact, so the omission of these well facilities would not change the significance of this impact under this alternative.	**Same as the proposed Project (LSM)** Sites 7 and 8 do not contribute to the significant impact, so the omission of these well facilities would not change the significance of this impact under this alternative.

TABLE 7-2
Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project

Impact	Proposed Project	Alternative 1: No Project	Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield	Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield	Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield	Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield
Impact BR-3. The Project would impact jurisdictional wetlands or waters of the United States.	**Less than Significant with Mitigation (LSM)** Project construction could impact jurisdictional wetlands and waters at Sites 8, 9, and 11. Mitigation Measure M-HY-1 would reduce the impacts at these sites to less-than-significant levels.	**Same as existing conditions (NI)** There would be no construction activities and no wetlands or waters would be impacted as a result.	**Same as the proposed Project (LSM)** Under the Project, Sites 1 and 4 do not contribute to the significant impact, so the omission of these well facilities per this alternative would not change the significance of this impact.	**Same as the proposed Project (LSM)** Under the Project, Sites 1 and 4 do not contribute to the significant impact, so the omission of these well facilities per this alternative would not change the significance of this impact.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Site 8 contributes to the significant impact. While the omission of this site would reduce overall impacts on jurisdictional waters, the impact level would be reduced but the impact would remain at LSM.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Site 8 contributes to the significant impact. While the omission of this site would reduce overall impacts on jurisdictional waters, the impact level would be reduced but the impact would remain at LSM.
Impact BR-4. Project construction would conflict with local tree preservation ordinances.	**Less than Significant with Mitigation (LSM)** Project construction would result in tree removal at 12 sites. Mitigation Measures M-BR-4a, M-AE-1b, and M-BR-4b would reduce impact to less-than-significant levels.	**Same as existing condition (NI)** There would be no construction activities and no trees would be removed.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Site 4 contributes to the significant impact. While the omission of this site would reduce the extent of tree removal in San Mateo County jurisdiction, trees would be removed at 11 other sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Site 4 contributes to the significant impact. While the omission of this site would reduce the extent of tree removal in San Mateo County jurisdiction, trees would be removed at 11 other sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Site 7 contributes to the significant impact. While the omission of this site would reduce the extent of tree removal in the Town of Colma's jurisdiction, trees would be removed at 11 other sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Site 7 contributes to the significant impact. While the omission of this site would reduce the extent of tree removal in the Town of Colma's jurisdiction, trees would be removed at 11 other sites.
Impact BR-5. Project operations could adversely affect candidate or sensitive special-status species.	**Less than Significant with Mitigation (LSM)** Project construction could result in adverse impacts to special-status species at five sites. Mitigation Measure M-NO-5 would reduce impact to less-than-significant levels.	**Same as existing condition (NI)** There would be no project operations and no special-status species would be affected.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Site 1 contributes to the significant impact. While the omission of the site would reduce the extent of operational impacts, special-status species could still be affected at four sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Site 1 contributes to the significant impact. While the omission of the site would reduce the extent of operational impacts, special-status species could still be affected at four sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Site 7 (On-site Treatment) contributes to the significant impact. While the omission of the site would reduce the extent of operational impacts, special-status species could still be affected at four sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Site 7 (On-site Treatment) contributes to the significant impact. While the omission of the site would reduce the extent of operational impacts, special-status species could still be affected at four sites.
Impact BR-7. Operation of the Project could adversely affect sensitive habitat types associated with Lake Merced.	**Less than Significant with Mitigation (LSM)** Project operation could increase water levels at Lake Merced, which could inundate sensitive habitats along the shores of Lake Merced. Mitigation Measures M-BR-7, M-HY-9a, and M-HY-9b would reduce impacts to less-than-significant levels.	**Same as existing condition (NI)** Water levels in Lake Merced would continue to fluctuate with varying hydrologic conditions, as they do now.	**Similar but slightly greater than the proposed Project (LSM)** Under Alternative 2A pumping near Lake Merced would be reduced, so lake levels would be expected to increase to higher levels than under the Project, potentially increasing the likelihood of inundating sensitive habitat.	**Similar but slightly greater than the proposed Project (LSM)** Under Alternative 2B pumping near Lake Merced would be reduced, so lake levels would be expected to increase to higher levels than under the Project, potentially increasing the likelihood of inundating sensitive habitat.	**Similar but slightly less than the proposed Project (LSM)** The Alternative would have slightly less impact on Lake Merced sensitive habitats because pumping would be redistributed to wells near Lake Merced, and water levels would not increase as much as they would with the Project.	**Same as the proposed Project (LSM)** Pumping would not be redistributed to wells near Lake Merced, so the impact would be the same as the Project.

TABLE 7-2
Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project

Impact	Proposed Project	Alternative 1: No Project	Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield	Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield	Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield	Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield
Impact BR-8: Operation of the Project could adversely affect wetland habitats and other waters of the United States associated with Lake Merced.	**Less than Significant with Mitigation (LSM)** Project operation could decrease water levels at Lake Merced at the end of the design drought and could also increase water levels during wet and normal years such that a net loss of wetland habitat would occur. Mitigation Measures M-BR-8, M-HY-9a, and M-HY-9b would reduce impacts to less-than-significant levels.	**Same as existing condition (NI)** Water levels in Lake Merced would continue to fluctuate with varying hydrologic conditions, as they do now.	**Similar but slightly greater than the proposed Project (LSM)** Under Alternative 2A pumping near Lake Merced would be reduced, so the decline in lake levels at the end of the design drought would be 54 percent less than with the Project. This would reduce the impact on decreasing lake levels at the end of the design drought, but would increase the impact on rising lake levels during wet and normal years, thus increasing impacts on wetland habitat.	**Similar but slightly greater than the proposed Project (LSM)** Under Alternative 2B pumping near Lake Merced would be reduced, so the decline in lake levels at the end of the design drought would be 54 percent less than with the Project. This would reduce the impact on decreasing lake levels at the end of the design drought, but would increase the impact on rising lake levels during wet and normal years, thus increasing impacts on wetland habitat.	**Similar but slightly greater than the proposed Project (LSM)** The Alternative would increase pumping in wells near the lake. This would reduce the impact on rising lake levels during wet and normal years, but would increase the impact on decreasing lake levels at the end of the design drought, thus increasing impacts on wetland habitat.	**Same as the proposed Project (LSM)** Because pumping would not be redistributed to wells near Lake Merced, this alternative would have the same impact as the Project.
Impact BR-9: Operation of the Project could adversely affect native wildlife nursery sites associated with Lake Merced.	**Less than Significant with Mitigation (LSM)** Project operation could affect water levels at Lake Merced which would inundate eucalyptus trees that support cormorant and heron rookeries. Mitigation Measures M-BR-7 and M-HY-9a would reduce impacts to less-than significant levels.	**Same as existing condition (NI)** Water levels in Lake Merced would continue to fluctuate with varying hydrologic conditions, as they do now.	**Similar but slightly greater than the proposed Project (LSM)** Under Alternative 2A pumping near Lake Merced would be reduced, so lake levels would be expected to increase to higher levels than under the Project, potentially increasing the likelihood of inundating eucalyptus trees.	**Similar but slightly greater than the proposed Project (LSM)** Under Alternative 2B pumping near Lake Merced would be reduced, so lake levels would be expected to increase to higher levels than under the Project, potentially increasing the likelihood of inundating eucalyptus trees.	**Similar but slightly less than the proposed Project (LSM)** The Alternative would have slightly less impact on Lake Merced eucalyptus trees because pumping would be redistributed to wells near Lake Merced, and water levels would not increase as much as they would with the Project.	**Same as the proposed Project (LSM)** Pumping would not be redistributed to wells near Lake Merced, so the impact would be the same as the Project.
Impact C-BR-1. Construction and operation of the proposed Project could result in significant cumulative impacts related to biological resources.	**Less than Significant with Mitigation (LSM)** The Project could result in significant cumulative impacts related to biological resources at all sites associated with effects on nesting birds, disturbance of riparian habitat and wetlands, and tree removal. Mitigation Measures M-BR-1a, M-BR-1b, M-BR-1c, M-BR-1d, M-BR-2, M-HY-1, M-BR-4a, M-AE-1b, and M-BR-4b would reduce impacts to less-than-significant levels.	**Same as existing conditions (NI)** There would be no construction activities. No new GSR well facilities would be constructed.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant cumulative impact related to special-status species. Site 1 contributes to impacts related to Coastal Riparian Scrub habitat, and Site 4 contributes to impacts related to local tree ordinances. The omission of these two sites would reduce cumulative impacts on these biological resources.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant cumulative impact related to special-status species. Site 1 contributes to impacts related to Coastal Riparian Scrub habitat, and Site 4 contributes to impacts related to local tree ordinances. The omission of these two sites would reduce cumulative impacts on these biological resources.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant cumulative impact related to special-status species. Site 8 contributes indirectly to impacts related to jurisdictional waters, and Site 7 contributes to impacts related to local tree ordinances. The omission of these two sites would reduce cumulative impacts on these biological resources.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant cumulative impact related to special-status species. Site 8 contributes indirectly to impacts related to jurisdictional waters, and Site 7 contributes to impacts related to local tree ordinances. The omission of these two sites would reduce cumulative impacts on these biological resources.

TABLE 7-2
Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project

Impact	Proposed Project	Alternative 1: No Project	Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield	Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield	Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield	Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield
Impact C-BR-2. The Project would not result in cumulative construction or operational impacts related to special-status species, riparian habitats, sensitive communities, wetlands, or water of the United States, or compliance with local policies and ordinances protecting biological resources at Lake Merced.	**Less than Significant with Mitigation (LSM)** Under cumulative conditions, the Project is expected to result in less dramatic water level fluctuations in most years than those for the Project alone, resulting in fewer impacts related to changes in water levels. Mitigation Measures M-BR-7, M-HY-9a, and M-HY-9b would reduce impacts to less-than-significant levels.	**Same as existing condition (NI)** Water levels in Lake Merced would continue to fluctuate with varying hydrologic conditions, as they do now.	**Similar but slightly greater than the proposed Project (LSM)** Under Alternative 2A pumping near Lake Merced would be reduced, so the decline in lake levels at the end of the design drought would be less than with the Project, but lake levels would increase more than with the Project in wet and normal years. This would increase the impact on sensitive habitat, wetlands, and eucalyptus trees around the lake.	**Similar but slightly greater than the proposed Project (LSM)** Under Alternative 2B pumping near Lake Merced would be reduced, so the decline in lake levels at the end of the design drought would be less than with the Project, but lake levels would increase more than with the Project in wet and normal years. This would increase the impact on sensitive habitat, wetlands, and eucalyptus trees around the lake.	**Similar but slightly greater than the proposed Project (LSM)** The Alternative would have slightly greater impacts on Lake Merced because there would be more pumping in wells near the lake at the end of the design drought, so water levels would be reduced further, resulting in loss of wetland habitat.	**Same as the proposed Project (LSM)** Because pumping would not be redistributed to wells near Lake Merced, this alternative would have the same impacts as the Project.
Geology and Soils						
Impact GE-3. The Project would expose people or structures to substantial adverse effects related to the risk of property loss, injury, or death due to fault rupture, seismic ground shaking, or landslides.	**Less than Significant with Mitigation (LSM)** Project operations would expose people or structures to substantial adverse effects related to the risk of property loss, injury, or death due to fault rupture, seismic ground shaking, or landslides at all sites. Mitigation Measure M-GE-3 would reduce impacts to less-than significant levels.	**Same as existing conditions (NI)** No new GSR well facilities would be constructed.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant impact related to ground shaking. The omission of these sites would reduce the number of new GSR facilities susceptible to ground shaking.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant impact related to ground shaking. The omission of these sites would reduce the number of new GSR facilities susceptible to ground shaking.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant impact related to ground shaking. The omission of these sites would reduce the number of new GSR facilities susceptible to ground shaking.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant impact related to ground shaking. The omission of these sites would reduce the number of new GSR facilities susceptible to ground shaking.
Impact GE-4. The Project would be located on a geologic unit or soil that is unstable, or that would become unstable.	**Less than Significant with Mitigation (LSM)** Project facilities would be located on unstable soils or soils that may become unstable at 10 sites. Mitigation Measure M-GE-3 would reduce impacts to less-than-significant levels.	**Same as existing conditions (NI)** No new GSR well facilities would be constructed.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Site 1 would contribute to the significant impact related to settlement. The omission of this site would reduce the number of new GSR facilities susceptible to settlement to nine sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Site 1 would contribute to the significant impact related to settlement. The omission of this site would reduce the number of new GSR facilities susceptible to settlement to nine sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Site 8 would contribute to the significant impact related to settlement. The omission of this site would reduce the number of new GSR facilities susceptible to settlement to nine sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Site 8 would contribute to the significant impact related to settlement. The omission of this site would reduce the number of new GSR facilities susceptible to settlement to nine sites.

TABLE 7-2
Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project

Impact	Proposed Project	Alternative 1: No Project	Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield	Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield	Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield	Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield
Hydrology and Water Quality						
Impact HY-1. Project construction activities would degrade water quality as a result of erosion or siltation caused by earthmoving activities or by the accidental release of hazardous construction chemicals during construction.	**Less than Significant with Mitigation (LSM)** Construction would result in earthmoving that if not properly managed could increase sediment loads in receiving water bodies, thereby adversely affecting water quality and designated beneficial uses for all sites. Mitigation Measure M-HY-1 would reduce impacts to less-than-significant levels for all sites.	**Same as existing conditions (NI)** There would be no construction activities that would degrade water quality.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant impact. Under this alternative, impacts on surface water quality would be slightly reduced because of the overall decrease in construction. However, the potential for surface water quality impacts would still occur at the remaining sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant impact. Under this alternative, impacts on surface water quality would be slightly reduced because of the overall decrease in construction. However, the potential for surface water quality impacts would still occur at the remaining sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant impact. Under this alternative, impacts on surface water quality would be slightly reduced because of the overall decrease in construction. However, the potential for surface water quality impacts would still occur at the remaining sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant impact. Under this alternative, impacts on surface water quality would be slightly reduced because of the overall decrease in construction. However, the potential for surface water quality impacts would still occur at the remaining sites.
Impact HY-2. Discharge of groundwater could result in minor localized flooding, violate water quality standards and/or otherwise degrade water quality.	**Less than Significant with Mitigation (LSM)** Well development, well pumping tests, initial well disinfection and excavation dewatering could result in increased sources of polluted runoff and may lead to degraded water quality at all sites except for the Westlake Pump Station. Mitigation Measure M-HY-2 would reduce impacts to less-than-significant levels.	**Same as existing conditions (NI)** There would be no wells constructed, and therefore no impacts from well testing or disinfection would occur.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant impact. Under this alternative, impacts on surface water quality would be slightly reduced because of the overall decrease in the total number of wells. However, the potential for water quality impacts resulting from groundwater discharge would still occur at the remaining sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 contribute to the significant impact. Under this alternative, impacts on surface water quality would be slightly reduced because of the overall decrease in the total number of wells. However, the potential for water quality impacts resulting from groundwater discharge would still occur at the remaining sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant impact. Under this alternative, impacts on surface water quality would be slightly reduced because of the overall decrease in the total number of wells. However, the potential for water quality impacts resulting from groundwater discharge would still occur at the remaining sites.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 contribute to the significant impact. Under this alternative, impacts on surface water quality would be slightly reduced because of the overall decrease in the total number of wells. However, the potential for water quality impacts resulting from groundwater discharge would still occur at the remaining sites.

TABLE 7-2
Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project

Impact	Proposed Project	Alternative 1: No Project	Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield	Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield	Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield	Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield
Impact HY-6. Project operation would decrease the production rate of existing nearby irrigation wells due to localized groundwater drawdown within the Westside Groundwater Basin such that existing or planned land use(s) may not be fully supported.	**Significant and Potentially Unavoidable with Mitigation (SUM)** Operation of the Project would cause significant well interference at 13 existing irrigation wells. Mitigation Measure M-HY-6 would reduce impacts to less-than–significant levels, except that the certainty of the mitigation measure cannot be assured until the existing irrigation well owners have agreed to allow the mitigation to take place on their property; thus, this impact is conservatively deemed significant and potentially unavoidable with mitigation.	**Similar but slightly less than the proposed Project (SU)** During a drought equivalent to the design drought, groundwater levels would decline to a point such that the production rate of existing wells may not fully support existing or planned land uses.	**Similar but slightly greater than the proposed Project (SUM)** Alternative 2A would decrease well interference at five existing irrigation wells and increase well interference at 12 existing irrigation wells. The level of significance for well interference at existing irrigation wells would not change compared to the Project. Mitigation Measure M-HY-6 would reduce impacts to less-than-significant levels, except that the certainty of the mitigation measure cannot be assured until the existing irrigation well owners have agreed to allow the mitigation to take place on their property; thus, this impact is conservatively deemed significant and potentially unavoidable with mitigation.	**Similar but slightly less than the proposed Project (SUM)** Alternative 2B would decrease well interference at five existing irrigation wells, but the level of significance for well interference at existing irrigation wells would not change compared to the Project. Mitigation Measure M-HY-6 would reduce impacts to less-than-significant levels, except that the certainty of the mitigation measure cannot be assured until the existing irrigation well owners have agreed to allow the mitigation to take place on their property; thus, this impact is conservatively deemed significant and potentially unavoidable with mitigation.	**Similar but slightly less than the proposed Project (SUM)** Alternative 3A would decrease well interference at 10 existing irrigation wells and increase well interference at seven existing irrigation wells. The level of significance for well interference at existing irrigation wells would not change compared to the Project, except that significant impacts would not occur at the Home of Peace Cemetery well. Mitigation Measure M-HY-6 would reduce impacts to less-than-significant levels, except that the certainty of the mitigation measure cannot be assured until the existing irrigation well owners have agreed to allow the mitigation to take place on their property; thus, this impact is conservatively deemed significant and potentially unavoidable with mitigation.	**Similar but slightly less than the proposed Project (SUM)** Alternative 3B would decrease well interference at five existing irrigation wells. The level of significance for well interference at existing irrigation wells would not change compared to the Project, except that significant impacts would not occur at the Home of Peace Cemetery well and the Holy Cross Cemetery well #1. Mitigation Measure M-HY-6 would reduce impacts to less-than–significant levels, except that the certainty of the mitigation measure cannot be assured until the existing irrigation well owners have agreed to allow the mitigation to take place on their property; thus, this impact is conservatively deemed significant and potentially unavoidable with mitigation.

TABLE 7-2
Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project

Impact	Proposed Project	Alternative 1: No Project	Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield	Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield	Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield	Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield
Impact HY-9. Project operation could have a substantial, adverse effect on water quality that could affect the beneficial uses of Lake Merced.	**Less than Significant with Mitigation (LSM)** Operation of the Project is predicted to cause lake levels at Lake Merced to decline by approximately 4 feet more than modeled existing conditions to a minimum monthly average of -2.5 feet City Datum, after the end of the design drought during recovery of the lake levels. These lake level impacts could cause significant water quality impacts that would have substantial adverse effects on the beneficial uses of Lake Merced. Mitigation Measure M-HY-9a and M-HY-9b would reduce impacts to less-than-significant levels.	**Similar but slightly less than the proposed Project (SU)** During a drought equivalent to the design drought, lake levels at Lake Merced are predicted to decline to -0.8 feet City Datum, a level at which substantial adverse effects on water quality and the beneficial uses of Lake Merced could occur.	**Similar but slightly less than the proposed Project (LSM)** Operation of the Project under this alternative is predicted to cause lake levels at Lake Merced to decline by approximately 2 feet more than under modeled existing conditions, to a minimum monthly average of -0.5 feet City Datum, after the end of the design drought during recovery of the lake levels. These lake level impacts could cause significant water quality impacts that would have substantial adverse effects on the beneficial uses of Lake Merced. Mitigation Measures M-HY-9a and M-HY-9b would reduce impacts to less-than-significant levels.	**Similar but slightly less than the proposed Project (LSM)** Operation of the Project under this alternative is predicted to cause lake levels at Lake Merced to decline by approximately 2 feet more than modeled existing conditions, to a minimum monthly average of -0.5 feet City Datum, after the end of the design drought during recovery of the lake levels. These lake level impacts could cause significant water quality impacts that would have substantial adverse effects on the beneficial uses of Lake Merced. Mitigation Measures M-HY-9a and M-HY-9b would reduce impacts to less–than–significant levels.	**Similar but slightly greater than the proposed Project (LSM)** Operation of the Project under this alternative is predicted to cause lake levels at Lake Merced to decline by approximately 5.2 feet more than modeled existing conditions, to a minimum monthly average of -3.7 feet City Datum, after the end of the design drought during recovery of the lake levels. These lake level impacts could cause significant water quality impacts that could have substantial adverse effects on the beneficial uses of Lake Merced. Mitigation Measures M-HY-9a and M-HY-9b would reduce impacts to less-than–significant levels.	**Similar to the proposed Project (LSM)** Operation of the Project under this alternative would not change effects on Lake Merced because pumping near the lake would be the same as under the Project. As with the Project, lake level impacts could cause significant water quality impacts that would have substantial adverse effects on the beneficial uses of Lake Merced. Mitigation Measures M-HY-9a and M-HY-9b would reduce impacts to less-than-significant levels.
Impact HY-14. Project operation may have a substantial adverse effect on groundwater depletion in the Westside Groundwater Basin over the very long term.	**Less than Significant with Mitigation (LSM)** Operation of the Project is predicted to cause groundwater storage in the Westside Groundwater Basin to decline by approximately 20,000 af more than under modeled existing conditions over the 47-year hydrologic modeling period. Mitigation Measure M-HY-14 would reduce impacts to less-than-significant levels.	**Similar but slightly more than the proposed Project (SU)** Groundwater storage volumes in the Westside Groundwater Basin are predicted to decline by approximately 28,000 af over the 47-year hydrologic modeling period.	**Same as the proposed Project (LSM)** Because this alternative maintains the Project yield, operation of the Project under this alternative is predicted to cause groundwater storage in the Westside Groundwater Basin to decline by approximately 20,000 af more than under modeled existing conditions over the 47-year hydrologic modeling period, the same as the Project. Mitigation Measure M-HY-14 would reduce impacts to less-than-significant levels.	**Similar but slightly less than the proposed Project (LSM)** Because this alternative reduces Project yield by 14 percent, operation of the Project under this alternative is predicted to cause groundwater storage in the Westside Groundwater Basin to decline by approximately 13,000 af more than under modeled existing conditions over the 47-year hydrologic modeling period, or 7,000 af less than the Project over the same time span. Mitigation Measure M-HY-14 would reduce impacts to less-than-significant levels.	**Same as the proposed Project (LSM)** Because this alternative maintains the Project yield, operation of the Project under this alternative is predicted to cause groundwater storage in the Westside Groundwater Basin to decline by approximately 20,000 af more than under existing conditions over the 47-year hydrologic modeling period, the same as the Project. Mitigation Measure M-HY-14 would reduce impacts to less-than-significant levels.	**Similar but slightly less than the proposed Project (LSM)** Because this alternative reduces Project yield by 16 percent, operation of the Project under this alternative is predicted to cause groundwater storage in the Westside Groundwater Basin to decline by approximately 12,000 af more than under modeled existing conditions over the 47-year hydrologic modeling period, or 8,000 af less than the Project over the same time span. Mitigation Measure M-HY-14 would reduce impacts to less-than-significant levels.

TABLE 7-2
Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project

Impact	Proposed Project	Alternative 1: No Project	Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield	Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield	Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield	Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield
Impact C-HY-2. Operation of the proposed Project would result in a cumulatively considerable contribution to cumulative impacts related to well interference.	**Significant and Unavoidable with Mitigation (SUM)** Operation of the Project under the cumulative scenario would cause significant well interference at 13 existing irrigation wells. Mitigation Measure M-HY-6 would reduce impacts to less-than-significant levels, except that the certainty of the mitigation measure cannot be assured until the existing irrigation well owners have agreed to allow the mitigation to take place on their property; thus, this impact is conservatively deemed significant and potentially unavoidable with mitigation.	**Similar but slightly less than the proposed Project (SU)** During a drought equivalent to the design drought, groundwater levels would decline to a point such that the production rate of existing wells may not fully support existing or planned land uses.	**Similar but slightly greater than the proposed Project (SUM)** Under the cumulative scenario, alternative 2A would decrease well interference at five existing irrigation wells and increase well interference at 12 existing irrigation wells. The level of significance for well interference at existing irrigation wells would not change compared to the Project. Mitigation Measure M-HY-6 would reduce impacts to less-than-significant levels, except that the certainty of the mitigation measure cannot be assured until the existing irrigation well owners have agreed to allow the mitigation to take place on their property; thus, this impact is conservatively deemed significant and potentially unavoidable with mitigation.	**Similar but slightly less than the proposed Project (SUM)** Under the cumulative scenario, alternative 2B would decrease well interference at five existing irrigation wells, but the level of significance for well interference at existing irrigation wells would not change compared to the Project. Mitigation Measure M-HY-6 would reduce impacts to less-than-significant levels, except that the certainty of the mitigation measure cannot be assured until the existing irrigation well owners have agreed to allow the mitigation to take place on their property; thus, this impact is conservatively deemed significant and potentially unavoidable with mitigation.	**Similar but slightly less than the proposed Project (SUM)** Under the cumulative scenario, alternative 3A would decrease well interference at 10 existing irrigation wells and increase well interference at seven existing irrigation wells. The level of significance for well interference at existing irrigation wells would not change compared to the Project, except that significant impacts would not occur at the Home of Peace Cemetery well. Mitigation Measure M-HY-6 would reduce impacts to less-than-significant levels, except that the certainty of the mitigation measure cannot be assured until the existing irrigation well owners have agreed to allow the mitigation to take place on their property; thus, this impact is conservatively deemed significant and potentially unavoidable with mitigation.	**Similar but slightly less than the proposed Project (SUM)** Under the cumulative scenario, alternative 3B would decrease well interference at five existing irrigation wells. The level of significance for well interference at existing irrigation wells would not change compared to the Project, except that significant impacts would not occur at the Home of Peace Cemetery well and the Holy Cross Cemetery well #1. Mitigation Measure M-HY-6 would reduce impacts to less-than–significant levels, except that the certainty of the mitigation measure cannot be assured until the existing irrigation well owners have agreed to allow the mitigation to take place on their property; thus, this impact is conservatively deemed significant and potentially unavoidable with mitigation.

TABLE 7-2
Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project

Impact	Proposed Project	Alternative 1: No Project	Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield	Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield	Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield	Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield
Impact C-HY-5. Operation of the proposed Project could have a cumulatively considerably contribution to cumulative impacts on beneficial uses of surface waters.	**Less than Significant with Mitigation (LSM)** Under the cumulative scenario, during a drought equivalent to the design drought, lake levels at Lake Merced are predicted to decline to -4.9 feet City Datum, a level at which substantial adverse effects on water quality and the beneficial uses of Lake Merced could occur. Mitigation Measures M-HY-9a and M-HY-9b would reduce impacts to less-than-significant levels.	**Similar but slightly less than the proposed Project (SU)** During a drought equivalent to the design drought, lake levels at Lake Merced are predicted to decline to -0.8 feet City Datum, a level at which substantial adverse effects on water quality and the beneficial uses of Lake Merced could occur.	**Similar but slightly less than the proposed Project (LSM)** Under the cumulative scenario, operation of the Project under this alternative is predicted to cause lake levels at Lake Merced to decline to a minimum monthly average of -2.3 feet City Datum, after the end of the design drought during recovery of the lake levels. These lake level impacts could cause significant water quality impacts that would have substantial adverse effects on the beneficial uses of Lake Merced. Mitigation Measures M-HY-9a and M-HY-9b would reduce impacts to less-than-significant levels.	**Similar but slightly less than the proposed Project (LSM)** Under the cumulative scenario, operation of the Project under this alternative is predicted to cause lake levels at Lake Merced to a minimum monthly average of -2.3 feet City Datum, after the end of the design drought during recovery of the lake levels. These lake level impacts could cause significant water quality impacts that would have substantial adverse effects on the beneficial uses of Lake Merced. Mitigation Measures M-HY-9a and M-HY-9b would reduce impacts to less-than–significant levels.	**Similar but slightly greater than the proposed Project (LSM)** Under the cumulative scenario, operation of the Project under this alternative is predicted to cause lake levels at Lake Merced to decline to a minimum monthly average of -6.5 feet City Datum, after the end of the design drought during recovery of the lake levels. These lake level impacts could cause significant water quality impacts that could have substantial adverse effects on the beneficial uses of Lake Merced. Mitigation Measures M-HY-9a and M-HY-9b would reduce impacts to less-than–significant levels.	**Similar to the proposed Project (LSM)** Under the cumulative scenario, operation of the Project under this alternative would not change effects on Lake Merced because pumping near the lake would be the same as under the Project. As with the Project, lake level impacts could cause significant water quality impacts that would have substantial adverse effects on the beneficial uses of Lake Merced. Mitigation Measures M-HY-9a and M-HY-9b would reduce impacts to less-than-significant levels.
Impact C-HY-8. Operation of the proposed Project would have a cumulatively considerably contribution to a cumulative impact related to groundwater depletion effect.	**Less than Significant with Mitigation (LSM)** Under the cumulative scenario, groundwater storage volumes in the Westside Groundwater Basin are predicted to decline by an approximately 45,000 af more than under modeled existing conditions over the 47-year hydrologic modeling period. Mitigation Measure M-HY-14 would reduce impacts to less-than-significant levels.	**Similar but slightly more than the proposed Project (SU)** Groundwater storage volumes in the Westside Groundwater Basin are predicted to decline by approximately 28,000 af over the 47-year hydrologic modeling period.	**Same as the proposed Project (LSM)** Because this alternative maintains the Project yield, operation of this Project alternative under the cumulative scenario is predicted to cause groundwater storage in the Westside Groundwater Basin to decline by approximately 45,000 af more than under modeled existing conditions over the 47-year hydrologic modeling period, the same as the Project. Mitigation Measure M-HY-14 would reduce impacts to less-than-significant levels.	**Similar but slightly less than the proposed Project (LSM)** Because this alternative reduces Project yield by 14 percent, operation of this Project alternative under the cumulative scenario is predicted to cause groundwater storage in the Westside Groundwater Basin to decline by approximately 35,000 af more than under modeled existing conditions over the 47-year hydrologic modeling period, or 10,000 af less than the Project over the same time span. Mitigation Measure M-HY-14 would reduce impacts to less-than-significant levels.	**Same as the proposed Project (LSM)** Because this alternative maintains the Project yield, operation of this Project alternative under the cumulative scenario is predicted to cause groundwater storage in the Westside Groundwater Basin to decline by approximately 45,000 af more than under existing conditions over the 47-year hydrologic modeling period, the same as the Project. Mitigation Measure M-HY-14 would reduce impacts to less-than-significant levels.	**Similar but slightly less than the proposed Project (LSM)** Because this alternative reduces Project yield by 16 percent, operation of this Project alternative under the cumulative scenario is predicted to cause groundwater storage in the Westside Groundwater Basin to decline by approximately 33,000 af more than under modeled existing conditions over the 47-year hydrologic modeling period, or 12,000 af less than the Project over the same time span. Mitigation Measure M-HY-14 would reduce impacts to less-than-significant levels.

TABLE 7-2
Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project

Impact	Proposed Project	Alternative 1: No Project	Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield	Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield	Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield	Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield
Hazards and Hazardous Materials						
Impact HZ-2. The Project would result in a substantial adverse effect related to reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment during construction.	**Less than Significant with Mitigation (LSM)** Construction of the Project could result in the accidental release of chemicals used during construction at all sites. Mitigation Measures M-HZ-2a, M-HZ-2b, M-HZ-2c, and, M-HY-1 would reduce impacts at all sites to less-than-significant levels.	**Same as existing conditions (NI)** There would be no construction activities and so no related hazardous material would be released.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 would contribute to the significant impact related to accidental release of hazardous construction chemicals. Site 1 would contribute to significant impacts related to hazardous building materials. Under this alternative, there would be no demolition of the existing restroom building at Site 1. The overall potential for these impacts would be reduced due to the omission of Sites 1 and 4.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 would contribute to the significant impact related to accidental release of hazardous construction chemicals. Site 1 would contribute to significant impacts related to hazardous building materials. Under this alternative, there would be no demolition of the existing restroom building at Site 1. The overall potential for these impacts would be reduced due to the omission of Sites 1 and 4.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 would contribute to the significant impact. Under this alternative, the overall potential for accidental release of hazardous construction chemicals would be reduced due to the omission of Sites 7 and 8.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 would contribute to the significant impact. Under this alternative, the overall potential for accidental release of hazardous construction chemicals would be reduced due to the omission of Sites 7 and 8.
Impact HZ-3. The Project would result in impacts from the emission or use of hazardous materials within 0.25 mile of a school during construction.	**Less than Significant with Mitigation (LSM)** Project construction would occur within 0.25 mile of a school at seven sites and adjacent to four well facility sites and the Westlake Pump Station. Mitigation Measure M-HY-1 and M-HZ-2c would reduce impacts at Sites 2, 3, 4, WLPS, and 19 (Alternate) to less-than-significant levels.	**Same as existing conditions (NI)** There would be no construction activities.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Site 4 would contribute to the significant impact related to use of hazardous materials near schools. Under this alternative, the overall potential for this impact would be reduced due to the omission of Site 4.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Site 4 would contribute to the significant impact related to use of hazardous materials near schools. Under this alternative, the overall potential for this impact would be reduced due to the omission of Site 4.	**Same as the proposed Project (LSM)** Under the Project, Sites 7 and 8 do not contribute to the significant impact, so the omission of these well facilities would not change the significance of this impact.	**Same as the proposed Project (LSM)** Under the Project, Sites 7 and 8 do not contribute to the significant impact, so the omission of these well facilities would not change the significance of this impact.

TABLE 7-2
Environmental Impacts of the CEQA Alternatives as Compared to the Proposed Project

Impact	Proposed Project	Alternative 1: No Project	Alternative 2A: Reduce Lake Merced Impacts and Maintain Project Yield	Alternative 2B: Reduce Lake Merced Impacts and Reduce Project Yield	Alternative 3A: Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield	Alternative 3B: Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield
Impact C-HZ-1: Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to hazards and hazardous materials.	**Less than Significant with Mitigation (LSM)** The Project could result in a cumulatively considerable contribution to cumulative impacts related to hazards and hazardous materials at all sites. Mitigation Measures M-HZ-2a, M-HZ-2b, M-HZ-2c, and M-HY-1 would reduce impacts to less-than-significant levels.	**Same as existing condition (NI)** There would be no construction activities. No new GSR well facilities would be constructed.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 would contribute to the significant cumulative impact related to accidental release of hazardous construction chemicals. Site 1 would contribute to significant cumulative impacts related to hazardous building materials. Site 4 would contribute to significant cumulative impacts related to use of hazardous materials near schools. Under this alternative, the overall potential for these impacts would be reduced due to the omission of Sites 1 and 4.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 1 and 4 would contribute to the significant cumulative impact related to accidental release of hazardous construction chemicals. Site 1 would contribute to significant cumulative impacts related to hazardous building materials. Site 4 would contribute to significant cumulative impacts related to use of hazardous materials near schools. Under this alternative, the overall potential for these impacts would be reduced due to the omission of Sites 1 and 4.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 would contribute to the significant cumulative impact related to accidental release of hazardous construction chemicals. Under this alternative, the overall potential for these impacts would be reduced due to the omission of Sites 7 and 8.	**Similar but slightly less than the proposed Project (LSM)** Under the Project, Sites 7 and 8 would contribute to the significant cumulative impact related to accidental release of hazardous construction chemicals. Under this alternative, the overall potential for these impacts would be reduced due to the omission of Sites 7 and 8.

7.5 ENVIRONMENTALLY SUPERIOR ALTERNATIVE

The CEQA Guidelines require the identification of an environmentally superior alternative to the proposed project (Section 15126.6[e]). If it is determined that the No Project Alternative would be the environmentally superior alternative, then the EIR shall also identify an environmentally superior alternative among the other Project alternatives (Section 15126.6[e][2]).

Construction of the proposed Project would cause significant and unavoidable noise and land use impacts (Impacts LU-1, NO-1, and NO-3) (see Section 5.2, Land Use, and Section 5.7, Noise and Vibration) from well drilling at nighttime and well facility construction during the daytime. Impacts LU-1 and NO-3 would be significant, even with mitigation, and there is no mitigation available to reduce the impact of nighttime construction conflicting with local noise standards (NO-1). In addition, aesthetic impacts of construction (Impact AE-1) (see Section 5.3, Aesthetics) would be significant and unavoidable at Site 7. All other construction impacts would have no impact, would be less than significant, or would be less than significant with implementation of mitigation measures. Operation of the proposed Project would cause significant and potentially unavoidable well interference impacts from pumping during take years at up to 13 existing irrigation wells. Mitigation would reduce these impacts to less than significant, except that the implementation of the mitigation measure cannot be assured until the existing irrigation well owners have agreed to allow the mitigation to take place on their property; for this reason, the impact is deemed to be significant and potentially unavoidable with mitigation (see Impact HY-6 in Section 5.16, Hydrology and Water Quality). All other operational impacts would either have no impact, would be less than significant, or would be less than significant with implementation of mitigation measures. The proposed Project would achieve all of the Project objectives.

The No Project Alternative would avoid the construction-related environmental impacts of the proposed Project, except for potential actions taken by the SFPUC or wholesale water customers to develop other dry-year water supplies. The No Project Alternative would avoid the significant and unavoidable land use and noise impacts (Impacts LU-1, NO-1, and NO-3) (see Section 5.2, Land Use, and Section 5.7, Noise and Vibration) and the significant and unavoidable visual impact (Impact AE-1) associated with the proposed Project (see Section 5.3, Aesthetics). This alternative would not achieve any of the Project objectives, and it would not fulfill the SFPUC's basic mission of providing a reliable water supply for its customers, because a new source of dry-year and/or emergency water supply would be unavailable for SFPUC customers. The No Project Alternative would not support conjunctive use of the South Westside Groundwater Basin, nor would it allow for in-lieu recharge of the Basin.

Both Alternative 2A and Alternative 2B were selected for consideration to allow evaluation of the effects of a project that would reduce impacts to Lake Merced by eliminating two wells near the lake. Alternative 2A maintains project yield by redistributing pumping, and Alternative 2A reduces project yield.

Alternative 2A (Reduce Lake Merced Impacts and Maintain Project Yield) would eliminate construction impacts at Sites 1 and 4, including significant and unavoidable land use and noise impacts (Impacts LU-1, NO-1, and NO-3) at both sites that would occur under the proposed Project (see Section 5.2, Land Use, and Section 5.7, Noise and Vibration). Construction impacts at the other sites would be the same as those of the proposed Project. During operations, this alternative would reduce the severity of water quality impacts (Impact HY-9) at Lake Merced through a 54 percent reduction in pumping in the Daly City area, but impacts of pumping would be significant while the lake is recovering from the design drought, similar to the proposed Project (see Section 5.16, Hydrology and Water Quality). This alternative would decrease the severity of well interference impacts at five existing irrigation wells, but increase the severity of well interference impacts (Impact HY-6) at 12 existing irrigation wells compared to the Project, due to a redistribution of pumping at GSR wells away from the Lake Merced area and an approximately 20 percent increase in pumping at Sites 5 through 15. Mitigation would reduce the well interference impacts to less-than-significant levels in all cases, except that the implementation of the mitigation measure cannot be assured until the existing irrigation well owners have agreed to allow the mitigation to take place on their property; for this reason, the impact is deemed to be significant and potentially unavoidable with mitigation. All other operational impacts would be less than significant with implementation of mitigation measures, which would be the same as the Project. Alternative 2A would have significant impacts at fewer sites than the Project during construction; however, impacts during operations would be approximately the same as the impacts of the Project, because mitigation measures would be equally effective at reducing impacts in either case. Because construction-period significant and unavoidable impacts of the proposed Project would be eliminated at two sites, impacts of Alternative 2A would be less severe than those of the proposed Project. In addition, Alternative 2A would achieve the Project objectives and would support the SFPUC's goal of providing a reliable dry-year groundwater supply during the 8.5-year design drought cycle.

Alternative 2B (Reduce Lake Merced Impacts and Reduce Project Yield), would eliminate construction impacts at Sites 1 and 4, including significant and unavoidable land use and noise impacts (Impacts LU-1, NO-1, and NO-3) at both sites that would occur under the proposed Project (see Section 5.2, Land Use, and Section 5.7, Noise and Vibration). Construction impacts at the other sites would be the same as those of the proposed Project. During operations, the alternative would reduce the severity of water quality impacts on beneficial uses (Impact HY-9) at Lake Merced through a 54 percent reduction in pumping in the Daly City area compared to the Project, but impacts of pumping would be significant while the lake is recovering from the design drought, similar to the proposed Project (see Section 5.16, Hydrology and Water Quality). This alternative would decrease the severity of well interference impacts (Impact HY-6) at five existing irrigation wells. All other operational impacts would be less than significant with implementation of mitigation measures, the same as the Project. Alternative 2B would have significant impacts at fewer sites than the Project during construction; impacts during operations would initially be less than the Project, but would become approximately the same as the impacts of the Project with implementation of mitigation, because mitigation measures would be equally effective at reducing impacts in either case. Therefore, because construction-period significant and unavoidable impacts of the proposed Project would be eliminated at two sites, the impacts of Alternative 2B would be less severe than those of the proposed Project; and because pumping would not be redistributed as it would be in Alternative 2A, operational impacts of Alternative 2B would be less severe than those of Alternative 2A and the proposed Project. Alternative 2B would not fully achieve the Project objectives, although it would meet most of them. Specifically, it would not fully support the SFPUC's goal to supply water reliably to customers in the event of emergencies and drought, because with the reduced yield associated with Alternative 2B, the SFPUC may not be able to limit systemwide rationing to 20 percent. The alternative would allow for the conjunctive use of the South Westside Groundwater Basin through coordinated use of SFPUC surface water and groundwater pumped by Partner Agencies and it would allow for in-lieu recharge of the Basin. However, the alternative would not provide the full 7.2-mgd dry-year and emergency pumping capacity needed to limit systemwide rationing to 20 percent during the 8.5-year design drought. The alternative would result in an approximately 1.0-mgd shortfall during each year of a severe drought. As a result, water rationing could increase to greater than 20 percent systemwide, which would be greater than currently included in the WSIP and thus under the proposed Project (SFPUC Resolution 08-200). In addition, the SFPUC and wholesale water customers may undertake other actions (e.g., groundwater development, water transfers) to meet their dry-year water supply needs, and each of these potential actions would likely have environmental impacts.

Alternative 3A (Reduce Impacts on Colma-area Existing Irrigation Wells and Maintain Project Yield) would eliminate construction impacts at Sites 7 and 8, including significant and unavoidable aesthetic impacts from tree removal at Site 7 that would occur under the proposed Project. Construction impacts at the other sites would be the same as those of the proposed Project. During operations, this alternative would reduce the severity of well interference impacts (Impact HY-6) on 10 existing irrigation wells at cemeteries in Colma, but would increase well interference impacts at seven existing irrigation wells compared to the Project, due to redistribution of pumping to GSR wells away from the Colma area (see Section 5.16, Hydrology and Water Quality). As a result, one existing irrigation well in Colma (Home of Peace Cemetery well) would not experience significant impacts, as it otherwise would under the proposed Project. Mitigation would reduce the significant well interference impacts to less-than-significant levels, except that the implementation of the mitigation measure cannot be assured until the existing irrigation well owners have agreed to allow the mitigation to take place on their property; for this reason, the impact has been deemed significant and potentially unavoidable with mitigation. All other operational impacts would be less than significant with implementation of mitigation measures, which would be the same as for the Project; however, impacts on Lake Merced water levels (prior to mitigation) would be slightly greater under this alternative. In addition, Alternative 3A would have significant impacts at fewer sites than the Project during construction, because this alternative eliminates significant construction aesthetic impacts at Site 7. No impacts would be more severe under this alternative than those of the Project with implementation of mitigation. However, the greater impact to Lake Merced water levels under Alternative 3A requires greater mitigation of impacts to Lake Merced water levels and would require additional supplemental water, redistribution of pumping, or discontinued pumping than under the proposed Project. Therefore, the operational impacts of Alternative 3A would be less severe than those of the Project or of Alternatives 2A or 2B, with the exception of slightly greater impacts associated with Lake Merced. Alternative 3A would fully achieve the Project objectives and support the SFPUC's basic goal of providing a reliable dry-year and emergency groundwater supply during the 8.5-year design drought cycle.

Alternative 3B (Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Project Yield) would eliminate construction impacts at Sites 7 and 8, including significant and unavoidable aesthetic tree removal impacts at Site 7 that would occur under the proposed Project (see Impact AE-1 in Section 5.3, Aesthetics). Construction impacts at the other sites would be the same as those of the proposed Project. During operations, the alternative would reduce the severity of well interference impacts (Impact HY-6) on 10 existing irrigation wells at cemeteries in Colma as compared to the Project (see Section 5.16, Hydrology and Water Quality). As a result, two existing irrigation wells in Colma (Home of Peace

Cemetery well and Holy Cross Cemetery well #1) would not experience significant impacts, as they otherwise would under the proposed Project. Mitigation would reduce the significant well interference impacts to less-than-significant levels, except that the implementation of the mitigation measure cannot be assured until the existing irrigation well owners have agreed to allow the mitigation to take place on their property; for this reason, the impact has been deemed significant and potentially unavoidable with mitigation. All other operational impacts would be less than significant with implementation of mitigation measures, which would be the same as for the Project. Alternative 3B would have significant impacts at fewer sites than the Project during construction, because this alternative eliminates significant construction aesthetic impacts at Site 7. In addition, Alternative 3B reduces well interference at two existing irrigation wells to less than significant. No impacts would be more severe under this alternative than the Project with implementation of mitigation. Therefore, the operational impacts of Alternative 3B would be less severe than those of the Project or of Alternatives 2A, 2B, or 3A. Alternative 3B would not fully achieve the Project objectives, although it would achieve most of them. Specifically, it would not fully support the SFPUC's goal to supply water reliably to customers in the event of emergencies and an 8.5-year drought. This alternative would allow for the conjunctive use of the South Westside Groundwater Basin through coordinated use of SFPUC surface water and groundwater pumped by Partner Agencies and it would allow for in-lieu recharge of the Basin. However, the alternative would not provide the full 7.2-mgd dry-year and emergency pumping capacity needed during the 8.5-year design drought. The alternative would result in an approximately 1.2-mgd shortfall during each year of a severe drought. As a result, water rationing could increase to greater than 20 percent systemwide, which would be greater than currently included in the WSIP and under the proposed Project. In addition, the SFPUC and wholesale water customers may need to undertake other actions (e.g., groundwater development, water transfers) to meet their dry-year water supply needs, and each of these potential actions would likely have environmental impacts.

Conclusion

As described above, none of the alternatives would reduce all the significant and unavoidable impacts of the proposed Project. Alternatives 2A, 2B, 3A, and 3B would cause significant and unavoidable impacts related to construction at one or two fewer sites than the Project; however, significant and unavoidable construction-related impacts would still occur at nine or 10 other facility sites, as they would under the proposed Project. Such impacts, although significant and unavoidable, would be temporary and would only occur for portions of the 16-month construction period. Alternatives 2A and 2B avoid the significant construction-period noise and land use impacts at Sites 1 and 4. Alternatives 3A and 3B avoid the significant and unavoidable aesthetic impact during construction associated with tree removal at Site 7.

Alternatives 3A and 3B would cause significant and potentially unavoidable well interference impacts during operation at one or two fewer existing irrigation wells than the Project; however, significant and potentially unavoidable well interference impacts would still occur at 11 or 12 existing irrigation wells, as they would under the proposed Project. The No Project Alternative would not cause significant and unavoidable construction impacts (since no construction would occur), but water levels at Lake Merced would continue to fluctuate as they do now under varying hydrologic conditions, and during a drought as severe as the design drought, lake levels would decline to a level that could have adverse water quality effects at Lake Merced. Because permanent operational impacts are considered more severe than temporary construction-period impacts, Alternative 3B (Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Yield) is the environmentally superior alternative, in that it would have significant and potentially unavoidable well interference impacts at fewer sites than the proposed Project or Alternatives 2A, 2B, or 3A. Alternative 3B (Reduce Impacts on Colma-area Existing Irrigation Wells and Reduce Yield) is therefore identified as the environmentally superior alternative, although, while it would meet most, it would not fully meet all of the Project objectives or WSIP goals.

7.6 ALTERNATIVES CONSIDERED BUT REJECTED FROM FURTHER ANALYSIS

As described under Section 7.3, GSR Alternatives Analysis, there is no alternative that would reduce all significant and unavoidable environmental impacts to a less than significant level and also meet most of the project objectives. The alternatives that were considered and then eliminated from further consideration are discussed below.

7.6.1 Eliminate Facility Sites with Significant and Unavoidable Construction-related Noise Impacts

Under this alternative, all sites with significant and unavoidable impacts for construction-related noise would be eliminated (see Section 7.3.2 [Impacts of the Proposed Project]). The following sites would be eliminated under this alternative: Sites 1, 3, 4, 5 (On-site Treatment), 9, 12, 14, 16, 18 (Alternate), and 19 (Alternate). It would allow the SFPUC to conjunctively manage the South Westside Groundwater Basin; however, it would not allow the SFPUC to increase the dry-year and emergency capacity of the Basin by 7.2 mgd during the 8.5-year design drought cycle.

This alternative is rejected from further consideration in this Draft EIR because the elimination of nine GSR sites would severely reduce the SFPUC's ability to provide sufficient water during the 8.5-year design drought. Operation of only 10 GSR wells would require nearly double the pumping rates proposed under the Project, which would be infeasible due to the lack of sufficient groundwater availability, in addition to the increased well interference effects at existing irrigation wells and Partner Agency municipal wells (MWH et al. 2008).

7.6.2 Construct and Operate 19 or More Well Facilities

Under this alternative, 19 or more new well facilities would be constructed and operated instead of the 16 sites proposed for the Project. The alternative would meet all the Project objectives. Specifically, it would provide for the conjunctive use of the South Westside Groundwater Basin, would increase the dry-year and emergency pumping capacity of the South Westside Groundwater Basin by an annual average 7.2 mgd, and would provide a new dry-year groundwater supply for SFPUC customers and increase water supply reliability during the 8.5-year design drought cycle.

However, the alternative is rejected from further consideration in the Draft EIR because of increased construction-related and operations-related environmental impacts and possible infeasibility. The alternative would construct more well facilities than the Project and, therefore, increase the environmental impacts from construction. The SFPUC, in cooperation with the Partner Agencies, completed an Alternatives Analysis Report (AAR) that identified and evaluated potential well facility sites to support the Project (MWH 2007). The analysis used evaluation criteria for selection of preferred facility sites. The AAR identified nine preferred sites with 14 wells. Following completion of the AAR, the SFPUC developed the Conceptual Engineering Report (CER) (MWH et al. 2008). Based on Project reviews during development of the CER, the SFPUC conducted analyses to determine potential effects of pumping the original 14 well locations on groundwater levels near the wells and potential impacts to existing irrigation wells in the Basin. Results of the analysis indicated that a more distributed network of wells than the original nine sites should be developed to reduce potential well interference impacts. The analysis determined that 16 wells distributed across the Basin would be the optimal number to reduce well interference effects at existing irrigation wells, Partner Agency municipal wells, and proposed GSR well sites. Further, expansion of the number of well facility sites would require that wells be located further out toward the edges of the Groundwater Basin where groundwater availability would be more limited, or closer to existing wells or proposed GSR well sites where well interference effects would be greater (MWH et al. 2008).

7.6.3 Construct Well Facilities at Different Locations within the South Westside Groundwater Basin

Under this alternative, a total of 16 well facilities, some of which would be constructed at locations different than those identified and evaluated for the proposed Project, would be constructed. The alternative would meet all the project objectives. Specifically, it would provide for the conjunctive use of the South Westside Groundwater Basin, would increase the dry-year and emergency pumping capacity of the South Westside Groundwater Basin by an average annual 7.2 mgd, and would provide a new dry-year groundwater supply for SFPUC customers and increase water supply reliability during the 8.5-year design drought cycle.

However, the alternative is rejected from further consideration in the Draft EIR because the selection of different sites, rather than the 19 sites (16 preferred sites and three alternate sites) evaluated for the proposed Project, would not reduce environmental impacts and may increase impacts beyond those identified for the proposed Project. The SFPUC and Partner Agencies completed an Alternatives Analysis Report (AAR) to evaluate potential well sites (MWH 2007). The AAR compared 48 potential well sites within the South Westside Groundwater Basin. The analysis evaluated potential well sites based on four evaluation criteria including the following:

- **Well Site Suitability** – including access to the site, the footprint of the site, underground obstructions and horizontal setback distances.
- **Groundwater System Considerations** – including potential well yield, groundwater quality, well interference potential, and geologic stability.

- **Distribution System Considerations** – including proximity to existing Partner Agency and SFPUC conveyance and treatment facilities.
- **Land Use Considerations** – including land ownership, property acquisition, ease of permitting, and local acceptance.

The evaluation criteria were applied to the preliminary well locations and a prioritized list of well locations was developed to meet the goal 7.2 mgd. The AAR identified nine preferred sites with 14 wells, and the nine sites were evaluated more fully to refine assumptions of the Basin properties at each preferred well site. Following completion of the AAR, two additional well sites were added to reduce well interference. The analysis performed by the SFPUC to identify the preferred well locations indicates that the remaining 32 well locations evaluated in the AAR would not reduce environmental impacts compared to the well sites in the proposed Project (MWH 2007; MWH et al. 2008).

7.6.4 Decreased Yield for all Proposed Wells

Under this alternative, a total of 16 well facilities would be constructed at the locations identified in the proposed Project (this could include a combination of any 16 of the 19 sites evaluated in this EIR, including Alternate location). However, the yield from each of these wells would be reduced to reduce significant groundwater impacts, such as well interference and water quality impacts at Lake Merced. The alternative would meet two of the four Project objectives. Specifically, it would provide for the conjunctive use of the South Westside Groundwater Basin and it would provide supplemental SFPUC surface water to Partner Agencies in normal and wet years and allow for in-lieu recharge through reduced groundwater pumping by Partner Agencies. The alternative would not create a dry-year and emergency pumping capacity of 7.2 mgd in the South Westside Groundwater Basin, and it would not provide a new dry-year groundwater supply for SFPUC customers and increase water supply reliability during the 8.5-year design drought cycle.

The alternative is rejected from further consideration in the Draft EIR because it would not meet most of the Project's basic objectives and therefore would not be a reasonable project alternative. Alternatives 2B and 3B would reduce the Project yield in a targeted manner so that significant groundwater impacts affecting water quality at Lake Merced (Impact HY-9) or well interference at existing irrigation wells in Colma (Impact HY-6) are reduced as much as feasible (see Section 5.16, Hydrology and Water Quality). An alternative that reduces yield equally at all of the well facilities would be less effective at reducing significant impacts, and therefore is not needed to provide decision-makers and the public with a reasonable range of alternatives for study.

7.6.5 Provide Water to Serve Less than an 8.5-year Design Drought Cycle

Under this alternative, a total of 16 well facilities would be constructed at the locations identified in the proposed Project. These wells would operate to meet the dry-year and emergency pumping capacity of the South Westside Groundwater Basin by 7.2 mgd in the event of an 8.5-year drought; however, pumping would cease before significant groundwater impacts would occur, resulting in water supplied for less than the full 8.5-year design drought cycle (should such an event ever occur). The alternative would meet three of the four Project objectives. Specifically, it would provide for the conjunctive use of the South Westside Groundwater Basin, it would provide supplemental SFPUC surface water to Partner Agencies in normal and wet years and allow for in-lieu recharge through reduced groundwater pumping by the Partner Agencies, and it would increase the dry-year and emergency pumping capacity of the South Westside Groundwater Basin to 7.2 mgd. However, the alternative would not provide a new dry-year groundwater supply for SFPUC customers nor increase water supply reliability during the entire 8.5-year design drought cycle.

The alternative is rejected from further consideration in the Draft EIR because the alternative would not meet the Project's most important objective, which is providing additional water for the entire 8.5-year design drought cycle and because it would not decrease significant impacts compared to the proposed Project. It is likely that significant well interference impacts would occur during the early years of a drought, because some of the existing irrigation wells have production capacity only slightly in excess of that needed to meet peak demand (see Table 5.6-13 [Estimated Peak Demand and 12-Hour Production Capacities] in Section 5.16, Hydrology and Water Quality). Therefore, pumping would need to be reduced early in the design drought cycle, and no additional environmental benefit would occur.

7.6.6 Construct a Year-round Desalination Plant for Drought

Under this alternative, the SFPUC would construct a desalination plant to provide water during drought years. The PEIR evaluated construction and operation of a 25-mgd year-round desalination plant as a means to provide supplemental water during all hydrological year types to blend with the regional system water, including supplemental water during drought years (San Francisco Planning Department 2008). The alternative would involve the construction of the Oceanside Seawater Desalination Plant on the west side of San Francisco near the existing Oceanside Water Pollution Plant. Under this alternative, 25 mgd of potable water supplies produced by reverse-osmosis technologies would be provided year-round to retail customers. The desalinated water would be introduced into the regional water system at Sunset Reservoir; this reservoir serves only customers in San Francisco and these customers would primarily receive desalinated water.

The San Francisco Public Utilities Commission rejected the alternative as infeasible at the time of approval of the WSIP in 2008 because construction and operation of a desalination facility raised unresolved environmental issues, including questions about protection of aquatic resources, water quality and brine disposal issues (SFPUC 2008). The desalination plant would require a significant amount of long-term energy use, which would increase emissions of greenhouse gases (unless powered by 100 percent non-GHG-generating energy sources). The Commission also rejected the alternative because the feasibility of a desalination plant was uncertain at that time, because it would require numerous additional permits and approvals and, therefore, would be unlikely that the facility could be approved within the ten years following approval of the WSIP. Moreover, the SFPUC determined that the alternative would be quite costly for the SFPUC, as set forth in Resolution 08-200.

This alternative is rejected from further consideration in the Draft EIR because, although the alternative would meet the Project's objective to provide a new dry-year water supply, it may not be cost effective to construct a year-round desalination plant for a dry-year water supply that would likely be needed less than 25 percent of the time on average. The unresolved environmental and regulatory compliance issues currently remain as they were when the Commission rejected this alternative during approval of the PEIR. Moreover, while the Commission rejected this alternative at the time of the 2008 WSIP approval (SFPUC Resolution 08-200), it continues to examine the feasibility of a year-round desalination plant in addition to a regional desalination plant, along with other opportunities and options to increase water supply to meet future demand and dry year needs. This ongoing evaluation was contemplated at the time of adoption of the WSIP and is part of the comprehensive assessment of water supply beyond 2018 and is appropriate for review in that context.

PROJECT DESCRIPTION

The purpose of the Regional Groundwater Storage and Recovery (GSR) Project (Project or proposed Project) is to further the use of the South Westside Groundwater Basin as an underground storage reservoir by storing water in the basin during wet periods for subsequent recapture during dry periods. This new dry-year water supply would be made available to the cities of Daly City and San Bruno, the California Water Company (Cal Water) in its South San Francisco service area (collectively referred to as Partner Agencies) and San Francisco Public Utilities Commission (SFPUC) wholesale water customers.

The SFPUC proposes to provide surface water, when available, to Partner Agencies, to be used by these agencies in lieu of pumping groundwater during normal and wet rainfall years. The Partner Agencies currently use groundwater as one of the sources of their drinking water supply. This supply would be partially replaced by surface water supplies from the SFPUC regional water system. The reduction of pumping by Partner Agencies would ultimately increase groundwater storage within the South Westside Groundwater Basin by up to 61,000 acre-feet (AF) (approximately 20 billion gallons). Stored groundwater would be utilized by pumping new Project wells during periods of insufficient surface water supplies (i.e., dry years). As part of the proposed Project, SFPUC would construct new groundwater production well facilities, which would be operated by either the Partner Agencies or SFPUC for pumping groundwater at a rate of 7.2 million gallons per day during dry years. The proposed Project would help meet the water supply reliability needs of all SFPUC customers during dry years and may provide some increased level of regional operational flexibility to respond and restore service during unplanned outages.

The proposed Project is one of several facility improvement projects identified in the San Francisco Region as part of the SFPUC's Water System Improvement Program (WSIP). The WSIP was adopted by the SFPUC in October 2008 to improve the SFPUC's regional water system with respect to water quality, seismic response, water delivery, and water supply to meet water delivery needs in the service area and establishes level of service goals and system performance objectives. The proposed Project's primary contribution to the WSIP goals is its ability to meet the water supply needs of SFPUC customers during drought years.

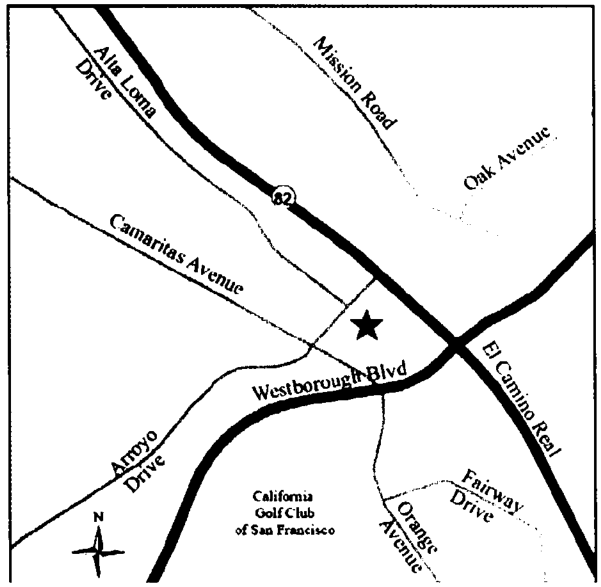
The proposed Project consists of 1) cooperative management of surface water and groundwater to optimize the water demand and supply balance; and 2) construction and operation of groundwater production well facilities on 16 of 19 potential sites in northern San Mateo County. Each groundwater well facility site would contain a groundwater production well, pump station, underground distribution piping, and utility connections. Some well facility sites would contain groundwater disinfection units and groundwater treatment facilities. Well facilities would connect to distribution systems for Daly City, San Bruno, Cal Water, and SFPUC. In addition, the Westlake Pump Station in Daly City may need to be upgraded and treatment facilities may need to be added to several well facility sites.

FINDING

This project may have a significant effect on the environment and an Environmental Impact Report is required. This determination is based upon the criteria of the State CEQA Guidelines, Sections 15063 (Initial Study), 15064 (Determining Significant Effect), and 15065 (Mandatory Findings of Significance), and for the reasons documented in the attached project description and description of potential environmental effects. (Documents are also available online at: http://www.sfgov.org/planning/mea.)

PUBLIC SCOPING PROCESS

Pursuant to the State of California Public Resources Code Section 21083.9 and CEQA Guidelines Section 15206, a public scoping meeting will be held to receive oral comments concerning the scope of the EIR at the following location, date, and time.



DATE: Thursday, July 9, 2009
6:15-7:00 p.m. Informational Session
7:00 p.m. Scoping meeting

LOCATION:
South San Francisco Municipal Services Building
Community Room
33 Arroyo Drive
South San Francisco, CA

Written comments will also be accepted at this meeting and until the close of business on **July 28, 2009**. Written comments should be sent to Bill Wycko, Environmental Review Officer, Regional Groundwater Storage and Recovery Project Scoping Comments, San Francisco Planning Department, 1650 Mission Street, Suite 400, San Francisco, CA 94103. They also may be submitted by fax to (415) 558-6409 or sent by email to diana.sokolove@sfgov.org.

If you work for a Responsible or Trustee Agency, we need to know the views of your agency regarding the scope and content of the environmental information that is germane to your agency's statutory responsibilities in connection with the proposed Project. Your agency may need to use the EIR when considering a permit or other approval for this proposed Project. Please include the name of a contact person in your agency.

Regional Groundwater Storage and Recovery Project

2008.1396E

~~Case No 2005.0164E~~

1.0 OVERVIEW AND BACKGROUND

The San Francisco Public Utilities Commission (SFPUC) is proposing the Regional Groundwater Storage and Recovery (GSR) Project (Project or proposed Project), which would be located in northern San Mateo County, California (see Figures 1, 2, and 3). To meet California Environmental Quality Act (CEQA) requirements, the San Francisco Planning Department's Major Environmental Analysis Division (MEA) will prepare and distribute an Environmental Impact Report (EIR) describing and analyzing the environmental effects of the proposed Project. This Notice of Preparation (NOP) provides a description of the Project background, a brief description of the proposed Project elements, and describes some of the proposed Project's potential environmental effects.

The purpose of the proposed Project is to further the use of the South Westside Groundwater Basin as an underground storage reservoir by storing water in the basin during wet periods for subsequent recapture during dry periods. This new dry-year water supply would be made available to the cities of Daly City and San Bruno, the California Water Company (Cal Water) in its South San Francisco service area (collectively designated as Partner Agencies) and SFPUC wholesale water customers.

SFPUC proposes to provide excess surface water when available to the Partner Agencies to be used by these agencies in lieu of pumping groundwater during normal and wet years. The Partner Agencies currently use groundwater as one of the sources of their drinking water supply. This supply would be partially replaced by surface water supplies from the SFPUC regional water system. The reduction of groundwater pumping by Partner Agencies would ultimately increase groundwater storage within the South Westside Groundwater Basin by up to 61,000 acre-feet[1] (AF) (approximately 20 billion gallons). Stored

[1] The SFPUC plans for an 8.5-year drought. Over this 8.5-year period, the SFPUC anticipates it will exercise its dry-year supplies after the first year of the drought. Therefore, the 61,000 AF of storage is assumed to be used over 7.5 years of the design drought, with wells operating at a maximum capacity of 7.2 MGD.

groundwater would be utilized by pumping new Project wells during periods of insufficient surface water supplies (i.e., dry years). As part of the proposed Project, SFPUC would create new groundwater production well facilities, which would be operated by either the Partner Agencies or SFPUC for pumping groundwater at a rate of up to 7.2 million gallons per day (MGD) during dry years. The proposed Project would help meet the water supply reliability needs of all SFPUC customers during dry years and may provide some increased level of regional operational flexibility to respond and restore service during unplanned outages.

The proposed Project is a component of the SFPUC's proposed Water System Improvement Program (WSIP) (see www.sfwater.org). The basic goals of the WSIP are to increase the reliability of the regional water system with respect to water quality, seismic response, delivery, and water supply to meet water delivery needs in the service area. A Program EIR (PEIR) for the WSIP was certified by the San Francisco Planning Commission, and the WSIP was adopted by the SFPUC on October 30, 2008. The PEIR addresses the potential environmental impacts of the WSIP facilities on a programmatic level and evaluates regional water supply alternatives. The proposed Project, which is the subject of this NOP, is one component of the WSIP[2]; implementation of this proposed Project would contribute to meeting the WSIP's overall goals and objectives.

For purposes of the WSIP PEIR, the SFPUC's regional water system facilities were subdivided into six regions: Hetch Hetchy, San Joaquin, Sunol Valley, Bay Division, Peninsula, and San Francisco. The proposed Project would occur in the San Francisco Region.

2.0 PROPOSED PROJECT FACILITIES

The proposed Project facilities would consist of new groundwater production well facilities within the South Westside Groundwater Basin (Basin); the facilities are designed to withdraw up to 7.2 MGD from the volume of stored groundwater directly resulting from Project-related reduced groundwater

[2] The Regional Groundwater Storage and Recovery Project was listed as the Conjunctive Use Project in the PEIR.

pumping in the Basin by Partner Agencies during normal and wet years. Up to 16 new groundwater well facilities would be constructed on 16 of the 19 potential sites in northern San Mateo County to supply the needed withdrawal capacity. Well facilities would be connected to Daly City, San Bruno, Cal Water, or SFPUC distribution systems. In addition, the existing Westlake Pump Station in Daly City may need to be modified and treatment facilities may need to be added.

Each groundwater well facility site would contain a groundwater production well, pump station, underground distribution piping, and utility connections. Each well facility would have a disinfection unit as required, unless it is near an existing disinfection unit that can accommodate the additional volume, in which case the well would be connected to the existing unit. Well facility sites where the groundwater may need treatment have been designed with appropriate treatment facilities.

3.0 ENVIRONMENTAL REVIEW PROCESS

As described above, the San Francisco Planning Commission certified the WSIP PEIR in October 2008. The PEIR addressed the potential environmental impacts of the WSIP facilities on a programmatic level and evaluated regional water supply alternatives. The PEIR is available on the San Francisco Planning Department website at www.sfgov.org/planning/mea.

The San Francisco Planning Department will prepare a project-specific EIR to evaluate the environmental effects of the proposed Project. The EIR will be prepared in compliance with the CEQA Guidelines Section 15161 and will address project-specific construction and operational impacts.

The first step in the environmental review process is the formal public scoping process, for which this NOP has been prepared. Following the public scoping period, a Draft EIR will be prepared and circulated for a 45-day public review period. Public comments on the Draft EIR will be accepted in writing during the review period or verbally at a formal public hearing to be held by the San Francisco Planning Commission. The San Francisco Planning Department then will prepare written responses to comments on environmental issues raised during the public review period, and a Response to Comments document will be prepared. That document will be considered by the San Francisco Planning

Commission, along with the Draft EIR and any revisions to the draft based on the response to comments, for certification as a Final EIR.

4.0 PUBLIC SCOPING MEETING

The San Francisco Planning Department will hold a public scoping meeting at the following location, date, and time.

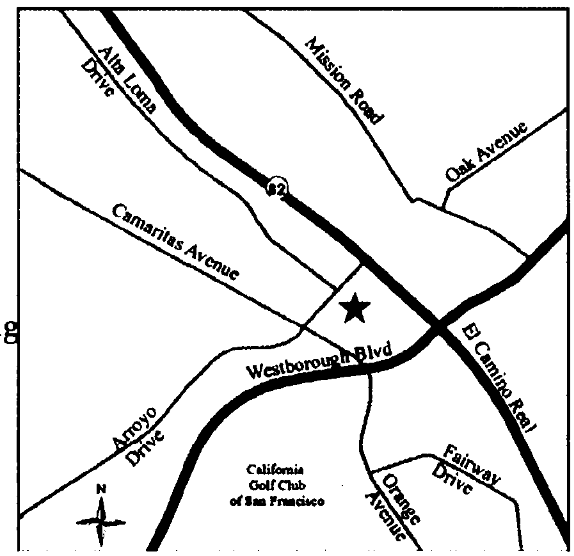
DATE: Thursday, July 9, 2009

6:15-7:00 p.m. Informational Session

7:00 p.m. Scoping meeting

LOCATION:

South San Francisco Municipal Services Building
Community Room
33 Arroyo Drive
South San Francisco, CA



The purpose of this meeting is to assist the Planning Department with its review of the proposed scope and content of the EIR as summarized in this NOP. The public will be given the opportunity to provide comment for consideration. The San Francisco Planning Department also will accept written comments on the scope of the EIR at the meeting or by mail, email, or fax until close of business (5:00 p.m.) on **July 28, 2009**. Written comments may be submitted by mail to the San Francisco Planning Department, Attn: Bill Wycko, Environmental Review Officer, Regional Groundwater Storage and Recovery Project Scoping Comments, 1650 Mission Street, Suite 400, San Francisco, CA 94103. They also may be submitted by fax to (415) 558-6409, or sent by email to diana.sokolove@sfgov.org.

5.0 PROJECT DESCRIPTION

5.1 Project Location

The proposed Project is located in the South Westside Groundwater Basin in San Mateo County, and the proposed facilities will be constructed in northern San Mateo County as shown in Figures 1, 2, and 3. The South Westside Groundwater Basin is located in San Mateo County within the larger Westside Groundwater Basin[3], which underlies both San Francisco and San Mateo counties. The Project is also located within the water service areas for the cities of Daly City, San Bruno, and Millbrae and within the Cal Water service area, which includes portions of South San Francisco, Colma, and unincorporated San Mateo County.

Groundwater well facilities would be constructed and operated at up to 16 locations in the cities of Colma, Daly City, South San Francisco, San Bruno, Millbrae, and unincorporated San Mateo County (see Figures 1, 2, and 3). Well facilities would be connected to existing water distribution pipelines owned by Daly City, San Bruno, Cal Water, and SFPUC. The Project also includes an upgrade of the existing Westlake Pump Station in Daly City to serve the proposed new well facility sites.

5.2 Project Objectives

The proposed Project is a regional groundwater storage and recovery project that is part of the SFPUC's WSIP. The overall goals of the WSIP for the regional water system are to maintain high-quality water; reduce vulnerability to earthquakes; increase water delivery reliability; meet customer water supply needs; enhance sustainability; and achieve a cost-effective, fully operational system. The proposed Project's primary contribution to the WSIP goals is its ability to meet the water supply needs of SFPUC customers during drought years. In addition,

---

[3] The Westside Groundwater Basin extends from western San Francisco south into San Mateo County. The Basin has an area of approximately 40 square miles and underlies Daly City, Colma, South San Francisco, San Bruno, Millbrae, and Burlingame. The Westside Groundwater Basin has been administratively divided at the San Francisco County-San Mateo County line. This is a political boundary, not a physical boundary. The portion of the basin that lies within San Francisco County is referred to as the North Westside Groundwater Basin. The portion of the basin that lies within San Mateo County is referred to as the South Westside Groundwater Basin. The Project would occur solely within the South Westside Groundwater Basin.

the Project may provide some increased level of regional operational flexibility to respond and restore service under unplanned outages.

The specific objectives of the proposed Project are to:

- Cooperatively manage the South Westside Groundwater Basin through the coordinated use of SFPUC surface water and the groundwater pumped by the Partner Agencies;
- Provide increased SFPUC surface water to the Partner Agencies in normal and wet years, resulting in a reduction of groundwater pumping by these agencies and an increase in groundwater storage in the South Westside Groundwater Basin;
- Increase the pumping capacity from the South Westside Groundwater Basin by up to 7.2 MGD to supply water during dry years and emergencies; and
- Provide a new dry-year groundwater supply for SFPUC customers and increase water supply reliability during the 8½-year design drought cycle.

5.3 Proposed Project

The proposed Project is a groundwater storage and recovery project, which includes the operation of new groundwater production wells and associated distribution and treatment facilities. This section includes a description of these proposed Project components.

5.3.1 Groundwater Storage and Recovery

The Partner Agencies currently supply potable water to their customers through a combination of groundwater from the South Westside Groundwater Basin and purchase of SFPUC surface water. The proposed Project would provide additional SFPUC surface water to the Partner Agencies during normal and wet years when sufficient surface water supplies are available. The Partner Agencies would reduce their groundwater pumping by a comparable amount and allow the groundwater basin to recharge naturally during these periods.

Figure 4 illustrates the increase in groundwater storage expected from a reduction in pumping during normal and wet years, as well the decrease in groundwater storage projected from an increase in pumping during dry years.

During normal and wet years, the volume of groundwater in the South Westside Groundwater Basin would naturally increase due to the reduced groundwater pumping, eventually reaching an increased storage volume of up to 61,000 AF. During dry or drought years, the Partner Agencies and SFPUC would pump previously stored groundwater. This new dry-year water supply would be made available to both the Partner Agencies and SFPUC wholesale customers under the terms of the Shortage Allocation Plan between the SFPUC and its wholesale customers[4]. A groundwater storage and recovery agreement would be negotiated by and between the SFPUC and Partner Agencies for groundwater and surface water management. Specifically, the agreement would cover water accounting; ownership principles; and operation, maintenance and replacement of facilities.

5.3.2 *Production Wells and Associated Facilities*

The proposed Project includes new groundwater production well facilities within the South Westside Groundwater Basin to withdraw the increased volume of stored groundwater at a rate of 7.2 MGD. Up to 16 new groundwater well facilities would be constructed on 16 of the 19 potential sites in northern San Mateo County. Of the 19 sites, 5 well facilities would connect to Daly City's distribution system, 3 well facilities would connect to San Bruno's distribution system, 4 well facilities would connect to Cal Water's distribution system, and 7 well facilities would connect to the SFPUC distribution system. In addition, the Westlake Pump Station in Daly City may be expanded and additional treatment facilities added.

Each groundwater well facility site would contain a groundwater production well, a pump station, underground distribution piping, and

---

[4] The Shortage Allocation Plan identified a water allocation method to be used to determine the share of water for wholesale customers during shortages caused by drought.

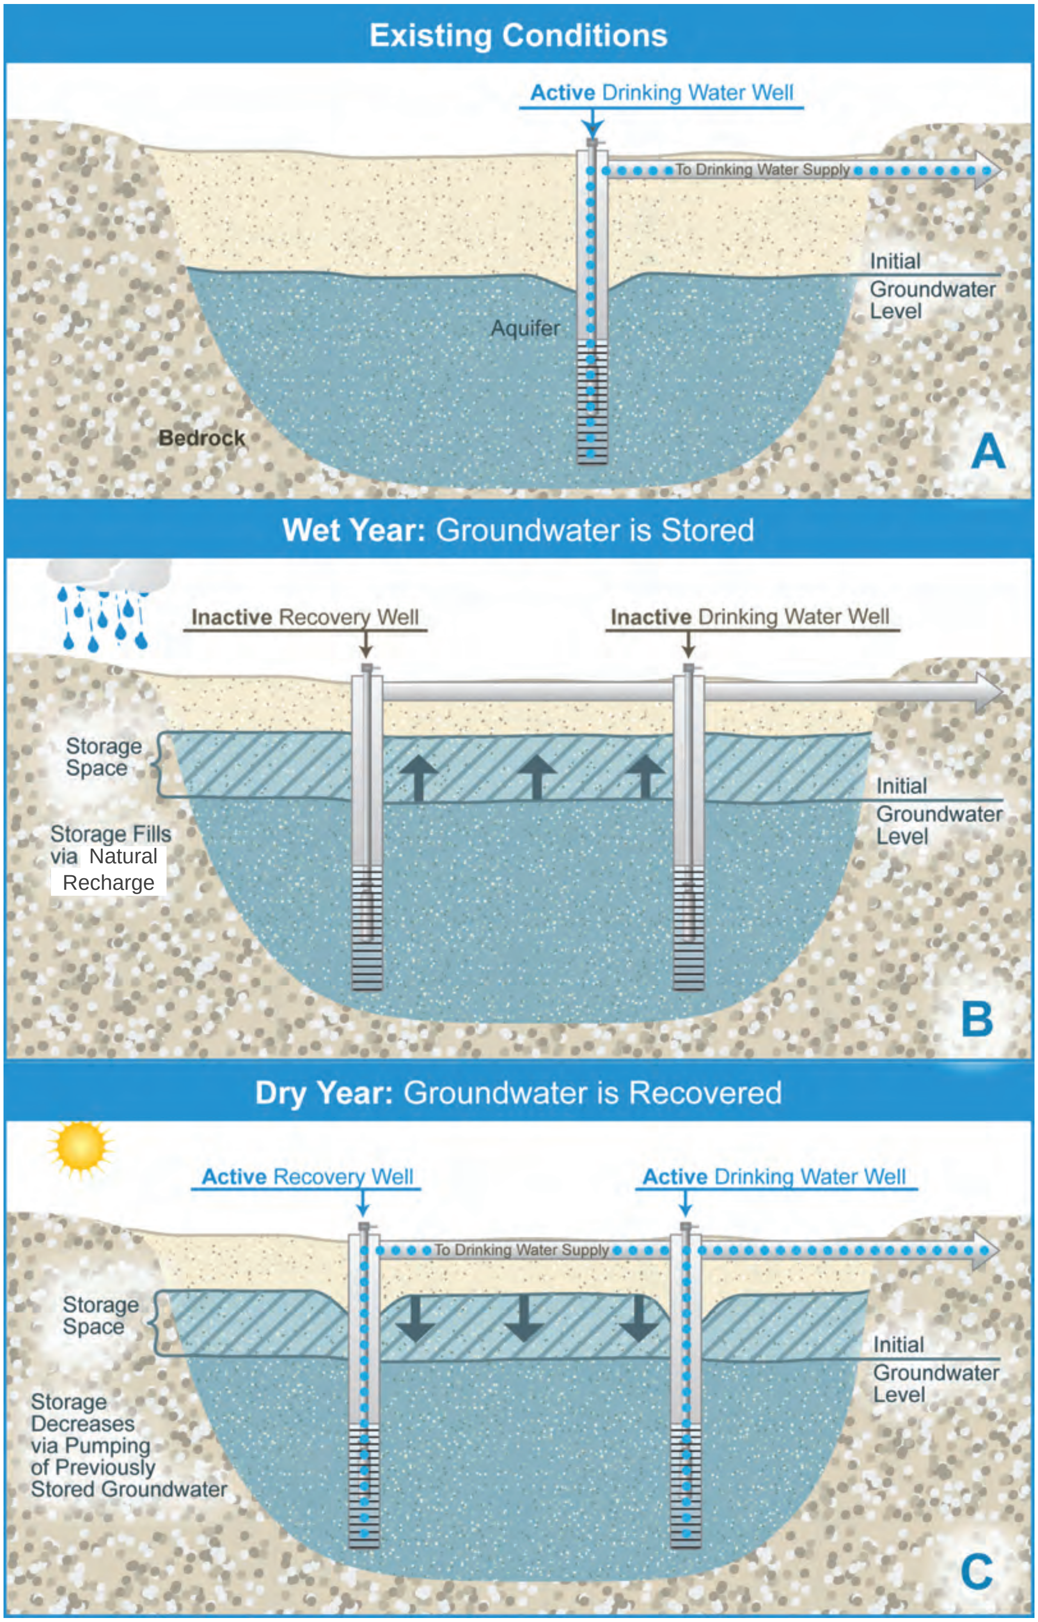


Figure (A) reflects the existing groundwater conditions, showing available storage space above the aquifer. In (B) the upward arrows represent the filling of the storage space with groundwater during wet years; in (C) the downward arrows represent the decline in stored water during dry years. The "Drinking Water Wells" represent the existing wells operated by the Cities of San Bruno and Daly City and California Water Service Company. The "Recovery Wells" represent the new wells that are proposed as part of the Project.

Groundwater Storage and Recovery

Regional Groundwater Storage and Recovery Project

Figure 4

utility connections. Each well facility also would have a disinfection unit, unless it is located near an existing disinfection unit that can accommodate the additional volume, in which case the well would be connected to the existing unit. Well facility sites where the groundwater may need treatment have been designed with appropriate treatment facilities (e.g., disinfection and manganese treatment). The facilities and the nature, extent and anticipated duration of construction activities are described further below.

Prior to confirming the final selected sites and full development of the groundwater well facilities, monitoring wells and test wells may be installed at the well facility sites to gather information about local groundwater characteristics and to determine the technical feasibility of each of the sites to produce sufficient volumes and quality of water for operation of a groundwater production well. If selected, sites would be converted from test wells to permanent production wells; pumps would be added, well enclosures would be built (fencing or building), disinfection units and treatment facilities would be constructed as needed, and utility and distribution pipelines would be installed.

A list of the 19 potential well facility sites and pump station upgrade is provided in Table 1.

a. The EIR will evaluate the environmental effects of the development of all 19 well facility sites, even though a maximum of 16 well facilities would be constructed.

Well Station Design

The SFPUC has considered institutional, regulatory, operational, maintenance, and technical information in the design of the well stations. Three well station types are included in the proposed Project:

- Type 1 - well only, building or fenced enclosure;
- Type 2 - well plus chemical treatment building; and
- Type 3 - well plus chemical treatment and filtration building.

Site-specific well station design characteristics are listed in Table 2 and described in detail below. These characteristics include proposed building type, pump type, water distribution system connection point, groundwater disinfection location, and the method that would be used to achieve agency-specific water quality goals (i.e., blending with surface water or treatment).

TABLE 2
Site-Specific Well Station Characteristics

a. Type 1 is Well Only; Type 2 is Well plus Chemical Treatment Building; Type 3 is Well plus Chemical Treatment and Filtration Building; see text below for further description of conceptual layouts.

b. Blending is the mixing of groundwater with other potable supply water

Buildings would be about 15 feet tall and constructed of concrete block. Acoustical louvers for noise reduction would be used. The buildings would be painted in neutral colors with anti-graffiti coating.

It is anticipated that all outdoor site lighting would be activated by motion-controlled sensors, with manual switching available for as-needed night operations. Facilities would be designed to meet California's energy efficiency standards outlined in Title 24 of the California Code of Regulations and use recycled materials to the extent possible.

Type 1 Conceptual Layout: Well-Only. The conceptual layout for the "well-only" type includes an approximately 40-foot by 20-foot building or fenced enclosure to house the wellhead, pump, piping, and associated electrical and control equipment.

Type 2 Conceptual Layout: Well plus Chemical Treatment. The conceptual layout for the "well with chemical treatment" type would consist of a 40-foot by 20-foot building to house the wellhead, pump, pipeline, and associated electrical and control equipment, plus an approximately 15-foot by 15-foot building extension for chemical storage and handling. Space would be provided onsite for disinfection, pH adjustment, and fluoride addition if needed.

Type 3 Conceptual Layout: Well plus Chemical Treatment and Filtration. The conceptual layout for the "well with chemical treatment and filtration" type would be similar to Type 2 but with the addition of a filtration system. The building dimensions would be approximately 25 feet by 80 feet. Filtration would be located only at well facilities that require manganese and/or iron removal. This well station type would be larger than the other types to provide space for the wellhead, treatment facilities, and filtration vessels. The filtration system consists of a series of vertical pressure vessels. The number and size of the pressure vessels would depend on the well yield and the number of wells connected to the filtration system. The backwash water from the system would connect to a nearby sanitary sewer. It is anticipated that filters would be backwashed, on average, once a day for 4 minutes.

Well Pumps

Each well facility site would contain either a submersible or above-ground pump. The selection of the pump type is based on the preference of the Partner Agency responsible for well operation. In most cases, the wells would be equipped with above-ground pumps. In comparison to submersible motors, above-ground motors are more efficient, have a longer service life, are more durable in cases where variable frequency drives are required, and are more accessible and thus easier to maintain. In cases where noise, visibility, or lack of space is an issue, submersible pumps would be used. Submersible motors are quieter to operate, but more difficult to maintain, because maintenance requires the removal of the entire pump assembly. Any wells that are in fenced enclosures (i.e., without buildings) have been designated for submersible pumps.

Utility and Distribution Piping

Underground piping would connect the wells to the local distribution systems or SFPUC water distribution system. In addition, underground piping would connect well facilities to the storm drain system and/or the sanitary sewer system to allow discharge of the initial flush of water. Chloraminated water would be de-chlorinated or sent to the local sanitary sewer system. Backwash from the manganese treatment facilities would also be sent to the local sanitary sewer system. The piping for all selected sites would consist of a total of approximately 4,600 feet of 6-inch pipe and 12,500 feet of 8-inch pipe. In general, the pipeline route would be excavated to a depth of 6 feet. The maximum width of the pipeline work area (including the trenches) would be 20 feet. The pipelines would be constructed using conventional open-cut trenching techniques. Above or underground electrical lines would also be installed from the groundwater well facilities to the nearest power source (PG&E facilities). The dimension of the trenches for the underground electrical lines would be smaller than those of the water pipelines.

Westlake Pump Station Upgrade

Upgrades to the Westlake Pump Station may be necessary to serve the well stations at Sites 2, 3 and 4. The upgrades would include new chemical storage tanks, replaced or upgraded chemical metering pumps, a resized transformer, and up to three new booster pumps to deliver the additional water into the distribution system.

5.3.3 *Construction Methods*

Monitoring Wells, Geotechnical Borings, and Test Wells

Prior to the selection and full development of the groundwater production well sites, monitoring wells and test wells may be installed and geotechnical borings may be drilled at the well facility sites to gather information about local groundwater characteristics and to determine the technical feasibility of each of the sites to produce sufficient volumes and quality of water for operation of a groundwater production well. Depending upon the results of the testing, well facility sites would be selected, and test wells converted to permanent production wells, which would consist of full development of the well facility site to include the addition of pumps to the wells, the addition of enclosures around the well, installation of disinfection units and treatment facilities as needed, and installation of utilities and distribution pipelines.

In the event that additional monitoring or test wells are needed, the selected site would need to be cleared of vegetation and graded for installation and drilling of the borehole. For monitoring wells, a borehole would be drilled to a depth of approximately 750 feet below ground. For test wells, one steel casing would be installed to a depth of approximately 50 feet, with a borehole drilled to a depth of approximately 550 to 700 feet. Equipment used for well drilling and construction would include a mounted drill rig on a support truck, pump and pick up trucks or trailers and similar equipment. Construction of a monitoring well would be completed in approximately three weeks, with construction activities occurring between 8:00 AM and 7:00 PM Monday through Friday only. Construction and testing of test wells would require approximately 4 weeks. Drilling would extend for about a week both during the day and night. If the results of the test wells were favorable and the wells were selected as permanent production well sites, then development of production well facilities would occur, as described below.

Additional geotechnical borings may be required and would be drilled to a depth of approximately 50 feet below ground surface (deeper if fill or soft soil is encountered). A boring would be completed in approximately two days. Drilling activities would occur between 8:00 AM and 7:00 PM Monday through Friday only.

Construction of Well Station Facilities

Each well facility site would include a construction staging area; some sites may have two optional locations for staging areas. The minimum size of the staging area would be 1,500 square feet. Staging areas would be fenced. Any temporary spoils (excavated material) storage would occur inside the staging areas.

Construction of facilities at the well sites would require site clearing and grubbing. Site excavation and grading would be minor, with grading to a maximum depth of 5 feet for the building foundation (if the well facility includes a building) and utilities underneath the building. After the foundation and utilities connections are constructed, the remainder of the building would be constructed and the well pump and other equipment installed, as needed. No significant near-surface groundwater is expected at any site; therefore dewatering for construction of project facilities is not anticipated. Diesel generators with self-contained fuel tanks may be used during construction. Construction equipment is expected to include: a front end loader, backhoe/excavator, fork lift, telescopic crane, cement mixer, concrete pump truck, compactor, hauling trucks, pump-setting rig, and arc welder.

It is estimated that during the peak construction period, the maximum number of construction workers at any one site would be 15.

Construction of Distribution and Utility Connections

In general, the pipeline routes would be excavated up to a depth of 6 feet. The width of pipeline construction zones would be generally 20 feet, and the width of the electrical connection construction zones would be less than 20 feet. The pipelines would be constructed using conventional open-cut trenching techniques. Construction equipment is expected to include: an excavator, front-end loader, hauling trucks, compactor, asphalt trucks, and arc welder. Diesel generators with self-contained fuel tanks may be used during construction. At some sites, pipeline excavation would generate excess soil (called spoils) that would be reused onsite (for engineering fill) or disposed of at a Class III non-hazardous waste disposal site. After pipeline placement, the trenched area would be restored to its original condition.

5.3.4 *Operation and Maintenance*

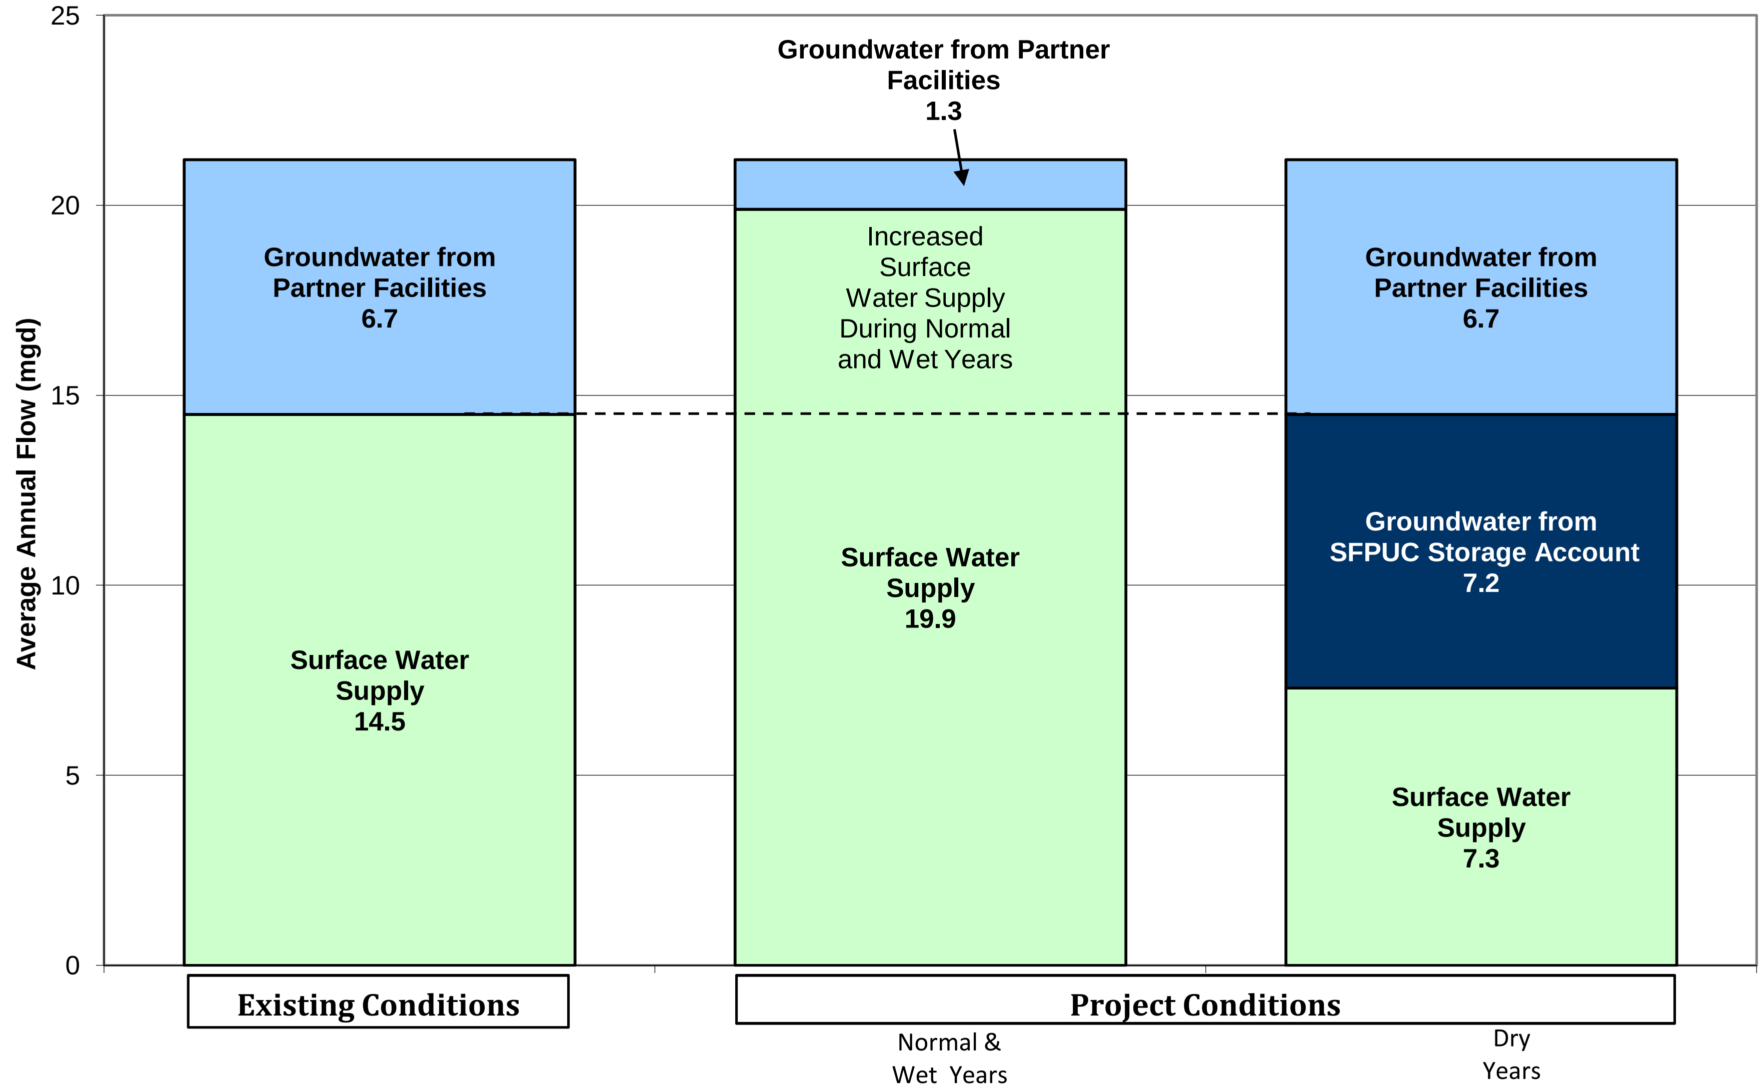
Project operations would be designed to allow natural recharge of the South Westside Groundwater Basin through reduced Partner Agency groundwater pumping, to provide up to 61,000 AF of increased groundwater in storage to be used by the SFPUC and Partner Agencies during drought conditions.

Figure 5 illustrates how the Project would change the source of water supply for the Partner Agencies. During normal and wet years, the portion of water supply coming from SFPUC surface water would increase compared to the existing condition. During dry years, the portion of water supply coming from groundwater would increase compared to the existing condition. For SFPUC wholesale water customers, the source of water supply would not change during normal and wet years; but the portion of groundwater delivered to some SFPUC customers would increase during dry years, compared to existing conditions.

An accounting of additional storage volumes (called the SFPUC Storage Account) would track the amount of water that has been stored during the normal and wet years and the amount of water pumped during dry years. The specific volumes shown in Figure 5 are based on historic rainfall and hydrology (MWH, 2007), but actual volumes in any given year would vary depending on several factors, including: 1) the final location and capacity of the project well facilities, 2) the availability of additional stored water in the SFPUC Storage Account, and 3) direction from the Operating Committee[5] regarding which wells should be used.

---

[5] It is expected that a Project agreement by and between SFPUC and the Partner Agencies would establish an Operating Committee. The role of the Operating Committee would be to monitor and track the SFPUC Storage Account, including any losses from the system, and establish pumping schedules for the project wells.



[1] Partner facilities are operated by City of Daly City, City of San Bruno, and Cal Water.

Source of Water Supply for Partner Agencies

Regional Groundwater Storage and Recovery Project

Figure 5

During normal and wet years, the proposed groundwater well facilities would be operated by SFPUC or by Partner Agencies only periodically for maintenance purposes. During dry years, the proposed groundwater well facilities would be operated by SFPUC or by Partner Agencies for additional water supply.

All well stations would be unmanned, but subject to remote monitoring and operation by the Partner Agency or SFPUC who would operate the well facility. Each well station would be visited daily when wells are operating for routine equipment checks, lasting approximately 30 minutes each. During normal and wet years, wells would be visited on a weekly basis, would be normally off, but regular exercising would be conducted. Longer term maintenance would include removal and repair or replacement of pumps, valves, and other equipment. Production wells may require redevelopment and/or rehabilitation on an infrequent basis.

6.0 PERMITS AND APPROVALS REQUIRED

The SFPUC may be required to obtain the following permits and approvals for Project construction and operation:

- Section 404 Permit from the U.S. Army Corps of Engineers (USACE) if the Project affects jurisdictional wetlands or waters of the U.S.
- U.S. Department of Veterans Affairs approval and National Environmental Policy Act (NEPA) review for Sites 14 and 15 at the Golden Gate National Cemetery.
- U.S. Fish & Wildlife Service Section 7 consultation under the federal Endangered Species Act, if the Project affects threatened or endangered species or their habitat.
- Review by the Advisory Council on Historic Preservation may be required if the Project affects properties listed on or eligible for the National Register of Historic Places.
- Permit amendments and approval of well construction and operation from the California Department of Public Health, Water Supply Division.
- Section 1602 Lake and Streambed Alteration Agreement from the California Department of Fish and Game if the Project could affect streambeds under California jurisdiction.
- Section 2081/2080.1 Incidental Take Permit from the California Department of Fish and Game if a "take" (to hunt, pursue, catch, capture,

or kill, or attempt the same) could occur to state-listed species as a result of the Project.

- California Department of Fish and Game Memorandum of Agreement if needed to ensure no effect to fully protected species.
- Preparation of a California Department of Toxic Substances Control Contaminated Soil Treatment Work Plan (required only if contaminated soil is encountered during construction).
- San Francisco Bay Regional Water Quality Control Board Discharge permits, if required, for emergency and/or maintenance water discharges, and for "overboard" pumping of well waters.
- San Francisco Bay Regional Water Quality Control Board Section 401 Certification, the state certification of the federal Section 404 Wetlands Permit.
- California Department of Transportation Encroachment permits to cross State roadways and Interstate Highways.
- State Water Resources Control Board Stormwater General Permit and Stormwater Pollution Prevention Plan, if more than one acre of land is disturbed.
- Bay Area Air Quality Management District permit for stationary equipment that may generate air pollutants (e.g., generators).
- EIR certification by the San Francisco Planning Commission.
- Board of Supervisors approval may be needed for funding appropriation or property rights acquisition.
- SFPUC approval, adoption of CEQA findings and mitigation monitoring and reporting program (MMRP).
- Adoption of CEQA findings and MMRP by local City Councils or Boards of Supervisors.
- San Francisco Historic Preservation Commission review of local, state and national landmarks and historical landscapes.
- Determination of Project consistency with park use by local Recreation and Park Commissions and approval of use of property under their jurisdiction.
- Approval of local Unified School District(s) for use of property under their jurisdiction.
- Approval of exterior design of proposed facilities on SFPUC property or right-of-way by the San Francisco Arts Commission.
- Agreements with Partner Agencies.
- Local Department(s) of Public Health approval of well construction and operation permits in accordance with California Department of Water Resources Standards.

- Local Department(s) of Public Health approval of Certified Unified Program Agencies (CUPA)/Hazardous Materials Business Plan for Project operations.
- Local Department(s) of Public Works approval of excavation permits, encroachment permits, and temporary occupancy permits for street space.
- Bay Area Rapid Transit (BART) encroachment permits to cross existing BART system.

7.0 PROPERTY RIGHTS ACQUISITION

Several types of property rights would be needed for Project construction and operation, as shown in Table 3. The process for acquiring right-of-way involves the preparation of deed and appraisal map, an appraisal of fair market value, negotiations with property owners, and condemnation (if necessary).

TABLE 3
Property Rights Proposed for Acquisition

Property Acquisition Type	Rights
Access Easement	Temporary or permanent rights to enter or cross another property
Pipeline Easement	Rights to install and maintain a pipeline over or across another property
Fee Acquisition	Purchase of all the property rights, land, improvements (if any), etc.
Encroachment Permit	Rights to encroach across a publicly-owned street or highway for pipeline or other purposes

Of the 19 potential well sites, 12 sites are on SFPUC fee-owned land or within SFPUC right-of-way. The other seven well sites are on other public and private parcels which would require an acquisition of property use rights for the well(s), connecting pipelines, and/or access. Lastly, several sites have lengthy connecting pipeline requirements that would most likely be constructed on a combination of public and private parcels.

8.0 CONSTRUCTION SCHEDULE

The proposed Project schedule expected at the time of this NOP includes construction of permanent well facilities and pipeline connections from April 2012 through approximately May 2014.

9.0 ENVIRONMENTAL ANALYSIS

9.1 Environmental Issues to be Addressed in the EIR

The EIR will address all environmental issue areas required under CEQA. The EIR will address environmental impacts of the proposed Project due to construction and operation activities and will propose mitigation measures for impacts considered to be significant. The following sections describe the anticipated environmental issues that will be addressed by the EIR.

9.1.1 Land Use and Visual Quality

Construction and operation of the proposed Project could affect land uses and visual quality of the Project sites and surrounding areas. Potential impacts to be evaluated in the EIR include:

- Temporary and permanent disruption or displacement of existing land uses during construction including construction impacts on such sensitive land uses as schools, residences and funeral homes, and the potential temporary closure of a portion of South San Francisco Linear Park to the public.
- Impacts on scenic vistas or visual character, including potential impacts on the visual character of Golden Gate National Cemetery, Woodlawn Cemetery, Greenlawn Memorial Park, and Lake Merced Golf Club.

9.1.2 *Geology, Soils and Seismicity*

Construction and operation of new well facilities and below-ground distribution pipelines and electrical power lines could result in site-specific impacts on or from local geology and soils conditions. Potential impacts to be evaluated in the EIR include:

- Seismic hazards and/or increased exposure of people and structures to seismic hazards, including impacts from ground-shaking in the event of an earthquake on the San Andreas fault or other Bay Area fault.
- Increased exposure of people or structures to geologic hazards (such as liquefaction, poor soil conditions, or unstable slopes) from construction in geologic hazard zones.
- Soil erosion potential from construction activities.
- Potential land subsidence from drawdown of the groundwater aquifer.

9.1.3 *Hydrology and Water Quality*

Construction and operation of the Project could affect surface water quality and could affect groundwater levels and quality in the Project area and in the South Westside Groundwater Basin as a whole. Potential impacts to be evaluated include:

- Changes in local groundwater quality and levels within the South Westside Groundwater Basin as a whole.
- Changes in drinking water quality due to use of treated groundwater.
- Alteration of drainage patterns and increase in stormwater flows due to increase in the amount of impervious surfaces.
- Degradation of surface water quality as a result of erosion and sedimentation, hazardous materials release during construction, and construction dewatering discharges.

9.1.4 *Biological Resources*

The proposed Project could result in a permanent loss of wetlands and sensitive habitats and could directly impact special-status wildlife and plant species. Temporary impacts to biological resources could result from proximity to construction activities, including noise, vibration, and dust. Potential impacts to be evaluated include:

- Impacts on wetlands and aquatic resources.
- Impacts on sensitive wildlife habitats and protected/heritage trees.
- Impacts on special-status wildlife and plant species – direct mortality and/or habitat effects.
- Conflicts with adopted conservation plans or other approved biological resources plans.

9.1.5 *Cultural Resources*

The proposed Project could affect archaeological, historical, or paleontological resources through ground-disturbing activities during construction, or by introducing new facilities that compromise the historic integrity of historic buildings or landscapes. Potential impacts to be evaluated include:

- Impacts on archaeological and paleontological resources.
- Impacts on the historical significance of a historic district, contributor to a historic district, or historic landscape. Of particular focus will be the proposed well facilities on 1920s Lake Merced Golf Club; the turn of the century Woodlawn Cemetery, the Cypress Lawn Cemetery, and the Golden Gate National Cemetery.
- Impacts on Native American cultural resources.

9.1.6 *Traffic, Transportation and Circulation*

Construction could have temporary impacts on traffic volumes, traffic safety, and parking in the vicinity of the well facility sites and at the Westlake Pump Station. Potential impacts to be evaluated EIR include:

- Temporary reduction in roadway capacity and increased traffic delays, including impacts from short-term closure of one parking and/or traffic lane. Impaired access to adjacent roadways and land uses.
- Temporary displacement of on- or off-street parking.
- Increased traffic safety hazards during construction.
- Long-term traffic increases during facility operation.

9.1.7 Noise and Vibration

Construction noise and vibration impacts from the proposed Project would be associated with facility construction activities, and therefore, would be temporary and short-term. Operation of the proposed pumps and treatment facilities could create permanent noise impacts. Potential impacts to be evaluated include:

- Impacts of construction noise and vibration on sensitive receptors in the vicinity of Project construction sites, especially such sensitive land uses as schools, health care facilities, cemeteries, funeral homes, and churches.
- Noise impacts from groundwater well station operation, including pumps and groundwater treatment facilities.

9.1.8 Recreational Resources

Construction could temporarily disrupt recreational uses in the vicinity of the well facility sites as a result of noise, dust, and temporary access restrictions. The EIR will evaluate the impact of the Project on recreational resources. Potential impacts to be evaluated include:

- Temporary and permanent impacts on recreational facilities, including but not limited to Lake Merced Golf Club and Linear Park in South San Francisco.

9.1.9 Other Environmental Issues

Other environmental issues that will be evaluated in the EIR include the Project's potential impacts on air quality and greenhouse gas emissions; public services and utilities, including the Project's beneficial effect on water supply; agricultural resources; hazards, including the potential hazards from chemical storage at the well sites; and energy resources.

The EIR also will evaluate any potential growth-inducing impacts that could result from implementation of the Project. The EIR also will address whether the Project could result in impacts that would be significant when combined with the impacts of other SFPUC or non-SFPUC projects occurring in the same geographic area as the Project and at the same time.

9.2 Alternatives

CEQA requires that an EIR evaluate a reasonable range of feasible alternatives to the project, or to the location of the project, that would attain most of the basic project objectives but that could avoid or substantially lessen any of the significant effects of the project. The EIR will identify the potentially significant impacts of the proposed Project. The findings of the EIR impact analysis will guide the refinement of an appropriate range of alternatives to be evaluated in the EIR that would avoid or substantially lessen significant impacts, while still meeting the project objectives. Alternatives suggested during the public scoping period would also be considered. The EIR will include a discussion of impacts associated with the No Project Alterative.

SCOPING SUMMARY MEMORANDUM

REGIONAL GROUNDWATER STORAGE AND RECOVERY PROJECT

October 2009

TABLE OF CONTENTS

This page left intentionally blank

1. INTRODUCTION AND BACKGROUND

1.1 INTRODUCTION

The San Francisco Planning Department is the lead agency for implementation of the California Environmental Quality Act (CEQA) for all projects sponsored by the City and County of San Francisco or conducted within San Francisco. The San Francisco Planning Department is preparing an Environmental Impact Report (EIR) on the San Francisco Public Utilities Commission's (SFPUC's) proposed Regional Groundwater Storage and Recovery Project (Project or proposed Project). The EIR, which will assess the potential impacts of the Project on the physical environment of the project area, is being prepared in accordance with CEQA. CEQA requires the preparation of an EIR when a proposed project could significantly affect the physical environment.

As part of the EIR process, the San Francisco Planning Department conducted a public scoping meeting in July 2009, soliciting comments from the public to help determine the scope of the EIR. This report describes the scoping process and summarizes the public's and regulatory agencies' comments received during scoping.

1.2 NOTICE OF PREPARATION

As the first step in the CEQA process, the San Francisco Planning Department published a Notice of Preparation (NOP) on June 24, 2009, announcing the anticipated preparation of the Draft EIR for the proposed Project. The NOP summarized the goals, objectives, and elements of the proposed Project, and presented the San Francisco Planning Department's determination that the proposed Project may have a significant effect on the environment. The NOP also described the requirement for preparation of an EIR on the proposed Project under CEQA. The San Francisco Planning Department determined that an EIR is the appropriate environmental document for the proposed Project. The NOP also described the scoping process and included information on a public scoping meeting. The scoping process, notification procedures, and outcome of the scoping meetings are described below, following a brief description of the proposed Project.

1.3 REGIONAL GROUNDWATER AND STORAGE RECOVERY PROJECT

The purpose of the Project is to further the use of the South Westside Groundwater Basin as an underground storage reservoir by storing water in the basin during wet periods for subsequent recapture during dry periods. This new dry-year water supply would be made available to the cities of Daly City and San Bruno, the California Water Company (Cal Water) in its South San Francisco service area (collectively referred to as Partner Agencies) and San Francisco Public Utilities Commission (SFPUC) retail water customers.

The SFPUC proposes to provide surface water, when available, to Partner Agencies, to be used by these agencies in lieu of pumping groundwater during normal and wet rainfall years. The Partner Agencies currently use groundwater as one of the sources of their drinking water supply. This supply would be partially replaced by surface water supplies from the SFPUC regional water system. The reduction of pumping by Partner Agencies would ultimately increase groundwater storage within the South Westside Groundwater Basin by up to 61,000 acre-feet (AF) (approximately 20 billion gallons). Stored groundwater would be utilized by pumping new Project wells during periods of insufficient surface water supplies (i.e., dry years). As part of the proposed Project, SFPUC would construct new groundwater production well facilities, which would be operated by either the Partner Agencies or SFPUC for pumping groundwater at a rate of 7.2 million gallons per day during dry years. The proposed Project would help meet the water supply reliability needs of all SFPUC customers during dry years and may provide some increased level of regional operational flexibility to respond and restore service during unplanned outages.

The proposed Project is one of several facility improvement projects identified in the SFPUC's Water System Improvement Program (WSIP). The WSIP was adopted by the SFPUC in October 2008 to improve the SFPUC's regional water system with respect to water quality, seismic response, water delivery, and water supply to meet water delivery needs in the service area and establishes level of service goals and system performance objectives. The proposed Project's primary contribution to the WSIP goals is its ability to meet the water supply needs of SFPUC customers during drought years. To address the potential environmental impacts of the WSIP, the San Francisco Planning Department prepared a Program EIR (PEIR) on the proposed WSIP, which was certified by the San Francisco Planning Commission on October 30, 2008 (San Francisco Planning Commission Motion No. 17734). At a project-level of detail, the PEIR evaluated the environmental impacts of the WSIP's water supply strategy and, at a program level of detail, it evaluated the environmental impacts of the WSIP's facility improvement projects, including the proposed Project.

The proposed Project consists of: 1) cooperative management of surface water and groundwater to optimize the water demand and supply balance; and 2) construction and operation of groundwater production well facilities on 16 of 19 potential sites in northern San Mateo County. Each groundwater well facility site would contain a groundwater production well, pump station, underground distribution piping, and utility connections. Some well facility sites would contain groundwater disinfection units and groundwater treatment facilities. Well facilities would connect to distribution systems for Daly City, San Bruno, Cal Water, and to the SFPUC regional water transmission system for delivery of blended surface and grounwater supplies to retail customers in San Francisco. In addition, the Westlake Pump Station in Daly City may need to be upgraded, and treatment facilities may need to be added to several well facility sites.

2. SCOPING MEETING PROCESS

2.1 PURPOSE OF SCOPING MEETING

The purpose of scoping is to solicit input from the public and agencies on the appropriate scope, focus, and content of the EIR. The San Francisco Planning Department will consider all of the input received during the scoping process in the preparation of the Draft EIR. The Draft EIR will describe the existing environmental conditions of the area that could be affected by the proposed Project and evaluate the potential effects of the proposed Project in accordance with CEQA. The comments provided by the public and agencies during scoping will help the San Francisco Planning Department identify pertinent issues, methods of analyses, and level of detail that should be addressed in the Draft EIR. The scoping comments will also provide the basis for developing a reasonable range of feasible alternatives that will be evaluated in the Draft EIR. The Draft EIR is scheduled to be available for public comment in summer 2010. In addition to facilitating public and regulatory agency input on the scope and focus of the Draft EIR, scoping allows the San Francisco Planning Department to explain the EIR process to the public and to identify additional opportunities for public comment and public involvement during the EIR process. CEQA requires that the public be informed about the significant environmental effects of a proposed project, and the ways in which those environmental effects can be avoided or reduced, before the project is approved.

2.2 NOTIFICATION OF SCOPING MEETING

The scoping period began on June 24, 2009, with the issuance of the NOP. A public scoping meeting was held on July 9, 2009, and written comments were accepted through July 28, 2009. Agencies and the public were notified about the availability of the NOP and the public scoping meeting date and location, and were provided with details on the comment process. The following methods of notification were used:

Mailing List. A mailing list was compiled, including approximately 1,500 contacts for affected federal, state, regional, and local agencies; federal, state, regional, and local elected officials; regional and local interest groups; member agencies of the Bay Area Water Supply and Conservation Agency (BAWSCA) within San Mateo County; other potentially affected groundwater and irrigation users; and land owners and residents within approximately 300 feet of the Project well facility sites.

NOP Form and Report. On June 24, 2009, the NOP Form and Report (Appendix A) were distributed via certified mail to 32 potentially affected agencies and the State Clearinghouse. The NOP Form was also sent via first-class mail to the entire mailing list.

Meeting Notification. Notice of the public scoping meeting was provided to individuals and the general public through the following means (see Appendix B):

- **Legal notices.** Notices of the public scoping meeting, including information on how to obtain a copy of the NOP and provide public comment, were placed in the legal classified section of the San Francisco Examiner (6/24/09) and San Mateo County Times (6/24/09).

- **Display ads.** Display ads with information about the public scoping meeting, including information on how to obtain a copy of the NOP and provide public comment, were placed in the San Francisco Examiner (date) and San Mateo County Times (date) by the PUC.

- **Locations where NOP was made available.** The NOP Form and Report were posted to the San Francisco Planning Department's website (www.sfgov.org/planning/mea) as well as the SFPUC project website (www.sfwater.org). A printed copy of the NOP was also provided to anyone who requested it from the San Francisco Planning Department or the SFPUC.

2.3 SCOPING MEETING

The public scoping meeting was held on July 9, 2009 at the South San Francisco Municipal Services Building at 33 Arroyo Drive in South San Francisco, California, and was attended by 33 individuals.

The meeting included a presentation on the environmental review process and the proposed Project, followed by a formal public comment period. Attendees interested in presenting verbal comments submitted speaker cards and were called upon to speak. The meetings concluded with closing remarks. A transcript of this meeting is provided in Appendix C. Appendix D contains copies of the scoping meeting presentation, handout agenda, fact sheet, comment cards, speaker cards and sign-in sheets.

Immediately prior to the scoping meeting, an Informational Session was held by the SFPUC at the scoping meeting location where attendees were invited to view Project display boards and ask questions of the SFPUC project team.

3. SCOPING COMMENTS RECEIVED

3.1 OVERVIEW

Table 1 lists comments received by commenter type and source. Six people spoke at the scoping meeting, and ten comment letters were received during the comment period. One additional comment letter was received after the close of the comment period. This additional written comment is included in this summary.

TABLE 1
Comments Received by Commenter Type and Source

Commenter Type	Comment Source
Federal Agency	• None
State Agencies	• Governor's Office of Planning and Research, State Clearinghouse and Planning Unit, Scott Morgan (Written Comment #1) • California Department of Transportation, Lisa Carboni (Written Comment #2) • California Department of Water Resources, Karl P. Winkler (Written Comment #3)
Regional and Local Agencies	• County of San Mateo Planning and Building Department, Melissa Ross (Written Comment #4) • Town of Colma, Laura Allen (Written Comment #5) • Bay Area Water Supply & Conservation Agency, Nicole M. Sandkulla (Written Comment #6) • Town of Colma, Andrea Ouse (Oral Comment #101) • Montara Water and Sanitary District, Paul Perkovic (Oral Comment #106)
Business	• Bold, Polisner, Maddow, Nelson, & Judson, Robert B. Maddow (BPMNJ) (Written Comment #7) • Kathryn Slater Carter (Oral Comment #103) • BPMNJ, Robert B. Maddow (Oral Comment #105)
Groups	• California Trout, Mondy Lariz (Written Comment #8) • Committee to Save Lake Merced, Jerry Cadagan (Written Comment #9) • Tuolumne River Trust, Peter Drekmeier (Written Comment #10) • Restore Hetch Hetchy, Bob Hackamack (Written Comment #11) • Tuolumne River Trust, Peter Drekmeier (Oral Comment #102) • Lakeshore Area Improvement Club, Jim Stark (Oral Comment #104)

3.2 SUBJECT AREA OF COMMENTS

This section presents a summary of the comments received during the scoping process period. Table 2 identifies the issue areas raised by individual commenters. The corresponding comment number is provided in parentheses at the end of each comment. A transcript of the oral comments from the public scoping meeting is provided in Appendix C. The written comments (by number) can be found in Appendix E.

Please note that some of the comments summarized below may not characterize the project or its potential effects correctly. It is not uncommon for scoping comments to misrepresent the proposed project. The meaning of the comment summaries has not been changed, even if the comments appear to be incorrect. This summary does not include commentary on the comments. The comments will be considered in preparation of the EIR.

Notice of Preparation

Comment: The commenter states that he was dismayed to find no mention of Lake Merced in the NOP. (#8, California Trout)

Comment: The commenter states that there are too few details in the project description found in the NOP. Nowhere in the NOP or related material presented at the scoping meeting is Lake Merced or the Tuolumne River mentioned. It is within these two water bodies that the potentially significant negative environmental effects of the Project might materialize. Amplifying the project description after the deadline for scoping comments has passed would seem inconsistent with the spirit of the scoping process. Based on the inadequacy of the detail in the project description, the NOP should be withdrawn at this time and reissued only when an adequately detailed project description is submitted by the SFPUC. (#9, Committee to Save Lake Merced)

Scope of EIR

Comment: Several commenters expressed uncertainty over whether the test wells warrant a categorical exemption under CEQA. The Town of Colma requested that the project description and any other available information about the test wells be provided to the Town of Colma for review and comment. The test wells and the rest of the Project are all part of the same reasonably foreseeable "project" under CEQA, and that the EIR should describe the construction and operational impacts of the test wells; provide information regarding rates of pumping to be used to test the stability of the underlying aquifer, planned draw-down of groundwater levels to evaluate subsurface hydrogeological conditions, and the potential for well testing to result in a cone of depression affecting nearby groundwater users). It is appropriate to include the test wells in the EIR, so that they cannot be placed in full operation until the EIR is certified and the Project is approved. (#101, Andrea Ouse, Town of Colma; #5, Town of Colma; #7, Bold, Polisner, Maddow, Nelson & Judson)

Comment: Commenters suggest that the EIR should look at the additional use of recycled water as a source of water for irrigation purposes. The EIR should address how the water recycling program could work in parallel with the proposed project a the EIR should include an assessment of potential impacts if recycled water is used. (#105, Robert B. Maddow, Bold, Polisner, Maddow, Nelson & Judson; #6, BASWCA)

Comment: The environmental impacts of planned upgrades to the Westlake Pump Station and the addition of treatment facilities at well facility sites should be addressed in the EIR. (#5, Town of Colma)

Comment: The EIR should present the detailed operation strategy for the proposed Project, including the individual facilities, along with a detailed hydrological and environmental impact analysis of the proposed Project and associated facilities based upon the known operational strategy. (#6, BAWSCA)

Comment: The EIR should clarify how the administrative board for the management of the Westside Basin was arranged, and asks if the SFPUC intends to include representatives from the neighboring jurisdictions, public representatives, and representatives from existing irrigators (cemeteries and golf courses). The purview of the administrative board also should be described, as well as regulations and administrative rules that will govern the Board and the South Westside Groundwater Basin, and the notification process and timing for review and comment by users on any proposed administrative regulations. Describe if the board (assuming there will be an oversight committee) has a right to dictate how much water can be pumped and if there will be pumping limits. The EIR should clarify the rules that the SFPUC and participating pumpers have agreed to that will govern the operation of the Project during wet, normal, and dry periods, as well as the development of additional groundwater capability to meet future local water supply reliability needs. (#6, BAWSCA; #5, Town of Colma)

Comment: The EIR should describe how the baseline data for existing groundwater users, such as irrigators, will be determined, and if there has been an assessment of their future needs and the associated impacts. (#5, Town of Colma)

Comment: The EIR should describe the jurisdiction the water providers would have over procedures for replacement of existing wells, which is currently permitted by the County. The EIR should describe if there will be another approval process that will have oversight in these requests. (#5, Town of Colma)

Comment: The EIR should describe the bases for the establishment of the various baseline quantity numbers provided in the NOP, including 1) the estimate of the quantity currently in storage in the groundwater basin, 2) how it was determined that 61,000 acre-feet of groundwater storage is available in the Westside Basin, 3) the method of determining that 7.2 million gallons a day would be pumped in dry years, and 4) the length of time it will take for the aquifer to be replenished or brought to the desired levels. (#5, Town of Colma)

Comment: The EIR should describe if there is a plan to assemble an agreement (Memorandum of Understanding) between the irrigators, water providers, and legislative bodies in each jurisdiction to define the various limits and protections for current and future activities. (#5, Town of Colma)

Comment: The EIR should describe if irrigation uses have been factored into the calculations for replenishing the water table. (#5, Town of Colma)

Comment: The project description must include information on the location of the distribution system extensions necessary to connect Project facilities to existing distribution lines. Issues addressed should include aesthetics impacts, street and on-street parking closures affecting traffic, parking, and emergency response, and any economic impacts on local businesses that would result in indirect impacts on the physical environment. (#5, Town of Colma)

Comment: The existing project description (provided with the NOP) is inadequate to allow for meaningful CEQA review for the following reasons:

1) It lacks definitions of critical terms such as "excess surface water", "dry, normal and wet" years, and "sufficient surface water supplies."
2) It lacks adequate information regarding the aquifer in question to give meaning and context to the stated Project purposes. For example, the total capacity, current storage volume, and unused capacity for future conjunctive use in the South Westside Groundwater Basin are not given.
3) It should spell out how the proposed Project integrates with SFPUC's plans for groundwater development in the North Westside Groundwater Basin.

The commenter states that many answers to these issues may be found in the "groundwater storage and recovery agreement" mentioned in the project description. If so, then that agreement should be publicly disclosed before preparation of the EIR, and the scoping process should occur after, not before, those critical details are revealed. (#302-3, Jerry Cadagan, Committee to Save Lake Merced)

Comment: If this is a regional project, why is the North Westside Groundwater Basin not included? (#11, Restore Hetch Hetchy)

Comment: The EIR should repeat the clarification made on Page 1, Footnote 1 of the NOP whenever the 8.5-year design drought cycle is discussed. (#6, BAWSCA)

Comment: The EIR should address the potential for other users of the basin, who are not participating in this Project, to affect the overall storage level in the basin and the amount of water potentially available for withdrawal under the Project. The EIR should discuss what mechanisms can be implemented to protect the Program Storage against withdrawal by other non-participating pumpers. (#6, BAWSCA)

Comment: The EIR should clarify exactly how the new dry-year water supply would be made available to Partner Agencies and SFPUC wholesale customers under the terms of the Shortage Allocation Plan between the SFPUC and its wholesale customers. If the intent is that the available Program Storage, as quantified by the SFPUC Storage Account, will be taken into consideration by the SFPUC when determining how much water is available for delivery and whether a shortage condition exists, the EIR should provide this clarity. (#6, BAWSCA)

Comment: The EIR should address how the Program Storage and associated Project facilities might be used during an emergency, what rules would be applied to such operations, and who the beneficiaries would potentially be. (#6, BAWSCA)

Comment: The EIR should provide the water supply availability criteria to be used to determine the conditions of a “normal”, “wet”, and “dry” year associated with Project operation. (#6, BASWCA)

Comment: The EIR should provide a definition of “excess surface water” that determines the amount of reduced groundwater pumping in normal and wet years. (#6, BASWCA)

Comment: The EIR should define the methods to determine the amount of groundwater in the storage account at any point in time. Also, the basis for estimating underground losses of stored water that is not subsequently available for recapture needs to be explained. (#6, BASWCA)

Project Alternatives

Comment: Several commenters suggested that the EIR look at the possibility of using stormwater as a component of the recharge of the basin. The EIR should look at recharge of the groundwater with stormwater even in wet years, thus decreasing reliance on the Tuolumne River. The EIR should study using treated stormwater runoff, since most of the cities have existing stormwater drainage systems. Preliminary inquiry into the injection of stormwater and/or recycled water to the aquifer in this regard was that local geological conditions do not lend themselves to effective use of injection wells. This issue needs to be examined and discussed in the EIR in greater detail, including consideration of using the soon-to-be-made-available public groundwater model to determine optimum locations for injecting stormwater and recycled water. (#105, Robert B. Maddow, Bold, Polisner, Maddow, Nelson & Judson; #102, Peter Drekmeier, Tuolumne River Trust; #103, Kathryn Slater-Carter; #10, Tuolomne River Trust; #9, Committee to Save Lake Merced)

Comment: The EIR should discuss what would be necessary to recharge more of the 75,000 acre feet vacant storage available in this aquifer and the time to accomplish refilling. (#11, Restore Hetch Hetchy)

Comment: If there are alternatives that consider different well locations than those listed in the NOP, the EIR should discuss the siting criteria used to select an alternative well site. (#6, BASWCA)

Comment: Discuss using recycled water and urban stormwater runoff after the first flushing rain as source to raise the level in Lake Merced for this recharge purpose. (#11, Restore Hetch Hetchy)

Permits and Approvals

Comment: The California Department of Public Health (CDPH) should be added to the list of permitting agencies. (#6, BASWCA)

Hydrology and Water Quality

Groundwater Levels

Comment: The EIR should study the potential settlement issues associated with the more active management of the aquifer, including recharging the aquifer and deleting a part of the aquifer. It appears there is a gradual decrease in the amount of water in the aquifer right now. (#101, Andrea Ouse, Town of Colma)

Comment: Several of the golf courses throughout the basin have switched from use of groundwater to use of recycled water, and they have worked hard and paid money to preserve the aquifer. The proposed doubling of production of groundwater from the aquifer is of concern to some owners of private wells who have the legal rights to groundwater use within the basin. Beyond the in-lieu pilot program, no one knows what will happen when the aquifer is refilled. The EIR should describe how the effects of refilling the aquifer will be measured, both from the standpoint of its long-term productivity and from the standpoint of the impact on private well owners who have legal right to use water from the aquifer. There is potential for negative impacts to the production wells of pumpers, including the golf clubs, particularly during dry years. Should water levels be depressed below the screened intervals of the well casings, there is possibility of long-term well damage. The impacts on private wells may require mitigation by the SFPUC, and this needs to be analyzed and disclosed in the EIR. The locations of the new extraction wells proposed by the SFPUC, and any new wells planned by their municipal partners, need to be fully disclosed and analyzed in the EIR, with detailed maps. The results of the analysis, to be determined by mutual interference modeling, needs to be fully disclosed and analyzed in the EIR and the mitigation plan. (#105, Robert B. Maddow, Bold, Polisner, Maddow, Nelson & Judson; #7, Bold, Polisner, Maddow, Nelson & Judson)

Comment: The EIR should address the effect of aquifer replenishment to the assessed amounts (61,000 acre feet) on whatever lies above the basin, and also the effect of lowering the water table on whatever lies above the basin. (#5, Town of Colma)

Comment: There is the possibility that the ratio of "stored" to future extracted water is not actually or even close to 1:1. There is the potential for new users, or the potential for the "stored" water to be lost (not remain within the aquifer or the portion that is utilized), or the actual "usable" available storage may not be accurate. Careful environmental and technical analysis of the actual storage capacity and the effects of its use are needed before the Project is approved. (#7, Bold, Polisner, Maddow, Nelson & Judson)

Groundwater Quality

Comment: Will contaminants be remobilized when the basin is refilled? Numerous gas stations are located throughout the urbanized area in the basin. Some may have had leakage problems with MTBE-supplemented fuel. Some contaminants may have adhered to the soil particles when water levels were lower, and as the water levels are raised, the contaminants may be remobilized. Beyond leaking underground storage tanks, contaminants might have been deposited in the basin through industrial activity long ago and during the time when the aquifer was being hit hard. (#106, Paul Perkovic, member of the Board of Directors of the Montara Water and Sanitary District; #105, Robert B. Maddow, Bold, Polisner, Maddow, Nelson & Judson; #5, Town of Colma)

Comment: The potential for water levels to decline, even temporarily, as a result of dry year pumping may negatively impact water quality by concentrating contaminants and minerals. There may also be a potential for mixing of waters (and minerals) that may not otherwise have occurred, which would be a cause of concern and should be analyzed in the EIR. (#7, Bold, Polisner, Maddow, Nelson & Judson)

Comment: The EIR should explain how the high nitrate and manganese concentrations in water from the aquifer will be handled during drought when about 7.2 mgd will be added to the diminished surface supply. Describe if wellhead treatment will be used to accomplish reduction of these two chemicals or of blending with system water take care of these problems. (#11, Restore Hetch Hetchy)

Comment: The EIR should discuss the reason(s) for providing disinfection facilities at each well as disinfection is not necessarily required under Title 22 of the California Code of Regulations. It should specify the type of disinfection method to be used (chlorine or chloramines) and discuss any blending impacts or water quality compatibility issues. (#6, BASWCA)

Comment: The EIR should include the site-specific water quality testing data which is required in the pre-design. (#6, BASWCA)

Comment: The EIR should include an assessment to determine the ability to meet water quality goals when blending under the planned operational scheme. Project documentation indicates this will be verified from water samples collected from the test wells in the pre-design phase. The commenter asks if sufficient information will be available at the time of the EIR analysis to confirm that blending is a viable method to achieve water quality goals. (#6, BASWCA)

Comment: The EIR should provide the details of the long term monitoring program which will be used to assess changes in local groundwater quality and levels within the South Westside Groundwater Basin as a whole. The program should include the development of a best practices plan to protect the groundwater basin if not already developed. (#6, BASWCA)

Comment: It is indicated in the documentation for this Project that Drinking Water Source Assessments will be performed during pre-design. The commenter asks if these assessments will be available for use in the EIR analysis. (#6, BASWCA)

Water Supply

Comment: The commenter asks if the rate of recharge for the basin has been calculated and how long the water supply will last given that during dry years there would be more water extracted. (#103, Kathryn Slater-Carter)

Comment: The commenter asks how the Project will stabilize the water supplies that would be available from Hetch Hetchy to meet the coastal needs, including within the Montara Water and Sanitary District and the Coastside County Water District. (#106, Paul Perkovic, member of the Board of Directors of the Montara Water and Sanitary District)

Comment: It would be prudent to include in Project plans emergency generators or backup generators in the well pump-housing and treatment facilities. (#106, Paul Perkovic, member of the Board of Directors of the Montara Water and Sanitary District)

Comment: The Bay Area Water Supply and Conservation agency has a very complex water allocation scheme for drought periods, which is based on historic use and recent use. If participating agencies take delivery of a much higher quantity of water from the SFPUC system during the recharge period, then would their groundwater allocation be much higher during a drought? (#106, Paul Perkovic, member of the Board of Directors of the Montara Water and Sanitary District)

Comment: The Department of Water Resources states that it strongly supports the concept of the Project, and recognizes the importance of this Project and similar groundwater storage projects that meet the State of California's future water supply needs. (#3, Department of Water Resources)

Comment: The EIR should address any effect of the Project on reducing the availability of water supplies provided by California Water Company to the Town of Colma and its residents, thus requiring the Town and its residents to acquire water from other sources, and to identify other sources that are available. (#5, Town of Colma)

Comment: The current Notice and Description did not mention the specific source of the surface water supply that would be used to replace the present well water being pumped. The concern is that more water will be drawn from other watersheds. Those sources must be acknowledged and their impacts shown and mitigation provided in the Project EIR. The EIR should present a water balance stating the source of replacement water and provide a detailed water balance for the SFPUC delivery system as a whole. The comment provides a list of surface water diversions and inputs that should be presented in the water balance. (#11, Restore Hetch Hetchy).

Comment: The EIR should include a groundwater recovery assessment. (#6, BASWCA)

Surface Water – Lake Merced

Comment: The Lakeshore Acres Improvement Club has been concerned with lake levels at Lake Merced. The EIR should examine Lake Merced water levels and respond to all the concerns that are already known regarding the lake's water levels. (#104, Lakeshore Area Improvement Club)

Comment: The commentor states that a significant contributing factor to the decline in Lake Merced lake levels during the 80's was excessive pumping from the Westside Basin, resulting in an overdraft condition of the aquifer. The EIR should analyze whether the Project would cause excessive aquifer pumping and resultant overdraft, resulting in significant harm to the environment. (#9, Committee to Save Lake Merced)

Comment: The EIR should discuss the "potential for the flow from the shallow aquifer/lake system toward the underlying aquifer from which nearby production wells withdraw water" in the South Westside Groundwater Basin south of Lake Merced (quote from the Draft WSIP PEIR). (#11, Restore Hetch Hetchy)

Comment: The EIR should discuss the lake level management plan for Lake Merced. (#6, BASWCA)

Surface Water – Tuolumne River

Comment: The EIR should address the impacts of what sounds like the diversion of an extra 6.7 million gallons of water per day from the Tuolumne River in wet years, in addition to what was studied in the WSIP EIR. Additional information will be available at the end of this year or early next year that was not available at the time of the WSIP EIR. The PUC is doing a biological study of the stretch of the river below Hetch Hetchy as part of the Kirkwood Powerhouse Agreement in 1988. (#102, Peter Drekmeier, Tuolumne River Trust)

Comment: The commenter states that in general the Tuolumne River Trust supports the concept of cooperative management of surface water and groundwater to optimize the water demand and supply balance. However, the trust has concerns that the Project could harm the Tuolumne River by increasing diversions in normal and wet years. The EIR needs to identify the source(s) of the additional surface water that would provide an additional 5.4 millions gallons per day to SFPUC customers in normal and wet years. It also should define wet, normal and dry years. (#10, Tuolumne River Trust)

Comment: Currently, 60 percent of the Tuolumne River is used for agricultural and urban uses, and even more water is diverted, causing significant impacts to the river ecosystem, including a decline in anadromous fish. Diverting more water from the river would exacerbate this problem. The commenter states that the WSIP PEIR analysis of the impacts on salmon and steelhead from diverting more water from the Tuolumne River was wholly inadequate. New information about potential impacts to the Tuolumne River from increasing diversion should be included in the EIR for the Project, such as the SFPUC study of biological resources in the stretch of the river downstream of the Hetch Hetchy Reservoir, expected to be completed by the end of 2009. (#10, Tuolumne River Trust)

Comment: The EIR should address comments submitted by the Department of Fish and Game on January 15, 2009 for the San Joaquin Pipeline System Project regarding the effect of increased diversions from the Tuolumne River on fish species in the river. (#10, Tuolumne River Trust)

Comment: Wet years do not result in "wasted" water. Wet years can provide better flows for juvenile salmon and steelhead, enabling them to get flushed out into the Bay and Ocean in higher numbers. The EIR should study the impacts of diverting additional water from the Tuolumne River on fish populations even in wet and normal years. (#10, Tuolumne River Trust)

Comment: Requirements for instream flows in the lower Tuolumne River are likely to increase as a result of the Federal Energy Regulatory Commission (FERC) relicensing process that will begin in 2011 and be completed in 2016. FERC actions must be considered in the CEQA analysis for the Project. (#10, Tuolumne River Trust)

Water Rights

Comment: The EIR should describe if the water in the South Westside Groundwater Basin is to be used for the purposes of supplying residential, commercial, agricultural and recreational needs of those who reside over the basin, or if there are plans to export the water to communities beyond the underlying limits of the basin. If the plans are to export the water, describe of this will affect the ability of existing users to access more of the water in the basin. Describe if those jurisdictions that are not Partner Agencies will be allowed to review any agreement made with customers not located directly over the basin. (#5, Town of Colma)

Comment: The EIR should describe if the current and future water rights of an established pumper will be preserved by their current standard (#5, Town of Colma).

Comment: The project description should identify the proposed management structure in terms of the assertion of authority over the aquifer. It should address whether the Project will change the rights and ownership of the water to include entities other than those that already have rights to the water (#101, Andrea Ouse, Town of Colma).

Comment: The commenter asks about the legal implications of the undertaking and the impact of the Project on private property owners' rights to extract water from the basin for productive, beneficial uses, including the potential for some wells to be rendered obsolete, or require deepening, or require users to make new pumping or water supply arrangements. (#105, Robert B. Maddow, Bold, Polisner, Maddow, Nelson & Judson)

Comment: The EIR should discuss the rights that municipalities, residents, and property owners that are located in the overlying lands of the South Westside Groundwater Basin have to the use of groundwater within the Basin. The comment also provides a summary of water use rights under California law. (#5, Town of Colma)

Comment: The EIR should address any reasonably likely effects of the Project on groundwater rights, including the effects of water storage during wet periods and water recapture during dry periods on the town of Colma and its residents' use of the groundwater. (#5, Town of Colma)

Comment: The EIR should describe the provisions the City of San Francisco plans to make to avoid or minimize any adverse effects on groundwater rights of overlying municipalities, including through project design or compensation. (#5, Town of Colma)

Comment: The EIR needs to address protection of existing overlying rights, including any existing overlying rights that are not currently utilized due to the use of recycled water for irrigation in areas served by the aquifer. If the SFPUC seeks to recover the 15,000 AF they have already stored, the EIR should indicate how the interests of the overlying owners will be protected – i.e. how will the SFPUC assure other pumpers that their water rights will not be impaired by this excess pumping? (#7, Bold, Polisner, Maddow, Nelson & Judson)

Water Supply Cost

Comment: What would be the cost of the increased use of Hetch Hetchy water, which is very expensive water, and would business owners see an increase in their water rates. Daly City is able to keep the cost down by also using groundwater? (#103, Kathryn Slater-Carter)

Comment: If Daly City, South San Francisco, and Cal Water are provided additional water from Hetch Hetchy instead of pumping groundwater, would these entities pay the current Hetch Hetchy wholesale price for this water or would it be treated as an advance of so many acre feet of water that could be drawn on in the future? Because the cost for Hetch Hetchy water increases each year, paying current prices to purchase water to allow recharge, and then drawing on that water in the future when the agencies otherwise would be paying much higher rates to purchase Hetch Hetchy water, would mean that the other Hetch Hetchy water users, the Bay Area Water Supply and Conservation Agency, are underwriting the cost of water to South City, Daly City, and Cal Water. It would seem fairer to treat it as an advance of water that is then repaid later by drawing on groundwater, and the payments for Hetch Hetchy water remain at an average use and escalating price to pay for the seismic improvement program. (#106, Paul Perkovic, member of the Board of Directors of the Montara Water and Sanitary District)

Comment: Energy costs for irrigation users of the aquifer should be analyzed in the EIR. (#7, Bold, Polisner, Maddow, Nelson & Judson)

Climate Change

Comment: The EIR must consider climate change in detail given that the Project is partially based on the premise that there will be undefined “excess” surface water available in the undefined “normal and wet years.” (#9, Committee to Save Lake Merced)

Land Use and Planning

Comment: The two potential Project sites located in Broadmoor are within unincorporated San Mateo County jurisdiction. Therefore, the SFPUC is required to submit a project description for review and determination of General Plan conformity pursuant to Government Code Section 65402. (#4, County of San Mateo)

Comment: The EIR should list the municipalities that are located in the overlying lands of the South Westside Groundwater Basin. The commenter asks if the Town of Colma, in particular, is located in these lands. (#5, Town of Colma)

Aesthetics

Comment: The commenter is concerned about the buildings associated with each well site, specifically their location and physical appearance. The Town of Colma tries to keep its policies in line with the Town's existing tranquil and serene environment. (#101, Andrea Ouse, Town of Colma)

Cultural Resources

Comment: If construction activities are proposed within the State's Right-of-Way (ROW), Caltrans requires documented results of a current (no more than 5 years old) archaeological record search at the Northwest Information Center of the California Historical Resources Information System before an encroachment permit can be issued. If warranted, a cultural resource study by a qualified, professional archaeologist in compliance with NEPA (if there is a federal action on the Project), CEQA, and PRC section Section 5024.5 (for state-owned historic resources), and Volume 2 of Caltrans "Standard Environmental Reference." (#2, California Department of Transportation)

Transportation and Circulation

Comment: Caltrans comments that, as lead agency, the San Francisco Planning Department is responsible for all Project mitigation, including any needed improvements to State Highways. The EIR should fully discuss the Project's fair share contribution, financing, scheduling, and implementation responsibilities as well as lead agency monitoring for all proposed mitigation measures. The Project's traffic mitigation fees should also be specifically identified. (#2, California Department of Transportation)

Comment: Any required roadway improvements must be completed prior to issuance of Project occupancy permits. Also, an encroachment permit is required when a project involves work in the State's ROW so the lead agency should ensure resolution of Caltrans concerns prior to submittal of the encroachment permit application. Traffic-related mitigation measures will be incorporated into the construction plans during the encroachment permit process. (#2, California Department of Transportation)

Comment: Because the proposed Project is located adjacent to State highway facilities, the EIR must evaluate traffic impacts on State facilities to determine if a Traffic Impact Study is warranted. In addition, Project vehicle trips and hours of operation should be discussed and street routes for vehicles should be identified. Use of the Caltrans guidance for preparation of traffic impact studies is recommended. (#2, California Department of Transportation)

Comment: Project work that requires movement of oversized or excessive load vehicles on State facilities requires a transportation permit. (#2, California Department of Transportation)

Comment: Caltrans encourages the San Francisco Planning Department to coordinate with Caltrans for all SFPUC WSIP projects, and provides a contact name and address. (#2, California Department of Transportation)

Cumulative Impacts

Comment: The Draft WSIP PEIR lists several golf courses located atop the aquifer that are successfully using recycled water for irrigation. The EIR should discuss the impact on aquifer recovery from conversion to using recycled water for additional golf courses and other irrigated landscapes that still pump from this aquifer or use system water for irrigation. (#11, Restore Hetch Hetchy)

Comment: The commenter expresses concern about the test wells and indicates that the test wells appear to be handled as a separate project and not encompassed as part of a cumulative review of the Groundwater Storage and Recovery Project. (#101, Andrea Ouse, Town of Colma)

Comment: The EIR needs to fully analyze the impacts of the Project and other groundwater-related projects in the area, including, but not limited to the SFPUC's proposed lake level restoration project for Lake Merced; the project to pump groundwater at production rates from the North Westside Basin; the variety of recycled water projects proposed in various portions of the land overlying the aquifer; and stormwater management projects being considered in the area, particularly to the extent they may involve detention basins. (#7, Bold, Polisner, Maddow, Nelson & Judson)

PROJECT DESCRIPTION

The purpose of the Regional Groundwater Storage and Recovery (GSR) Project (Project or proposed Project) is to further the use of the South Westside Groundwater Basin as an underground storage reservoir by storing water in the basin during wet periods for subsequent recapture during dry periods. This new dry-year water supply would be made available to the cities of Daly City and San Bruno, the California Water Company (Cal Water) in its South San Francisco service area (collectively referred to as Partner Agencies) and San Francisco Public Utilities Commission (SFPUC) wholesale water customers.

The SFPUC proposes to provide surface water, when available, to Partner Agencies, to be used by these agencies in lieu of pumping groundwater during normal and wet rainfall years. The Partner Agencies currently use groundwater as one of the sources of their drinking water supply. This supply would be partially replaced by surface water supplies from the SFPUC regional water system. The reduction of pumping by Partner Agencies would ultimately increase groundwater storage within the South Westside Groundwater Basin by up to 61,000 acre-feet (AF) (approximately 20 billion gallons). Stored groundwater would be utilized by pumping new Project wells during periods of insufficient surface water supplies (i.e., dry years). As part of the proposed Project, SFPUC would construct new groundwater production well facilities, which would be operated by either the Partner Agencies or SFPUC for pumping groundwater at a rate of 7.2 million gallons per day during dry years. The proposed Project would help meet the water supply reliability needs of all SFPUC customers during dry years and may provide some increased level of regional operational flexibility to respond and restore service during unplanned outages.

The proposed Project is one of several facility improvement projects identified in the San Francisco Region as part of the SFPUC's Water System Improvement Program (WSIP). The WSIP was adopted by the SFPUC in October 2008 to improve the SFPUC's regional water system with respect to water quality, seismic response, water delivery, and water supply to meet water delivery needs in the service area and establishes level of service goals and system performance objectives. The proposed Project's primary contribution to the WSIP goals is its ability to meet the water supply needs of SFPUC customers during drought years.

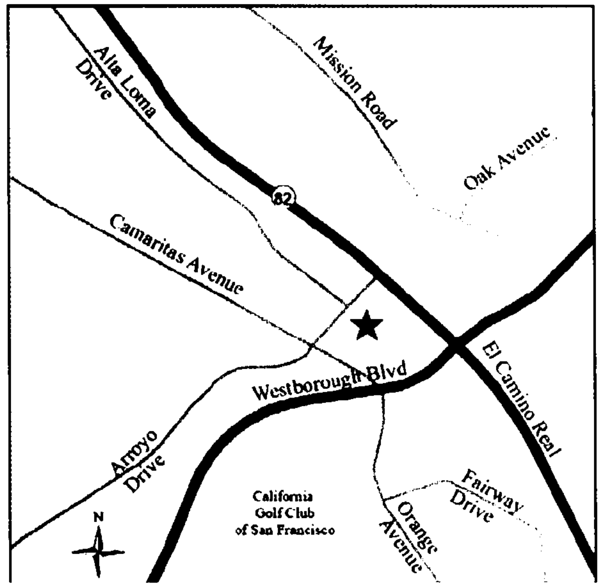
The proposed Project consists of 1) cooperative management of surface water and groundwater to optimize the water demand and supply balance; and 2) construction and operation of groundwater production well facilities on 16 of 19 potential sites in northern San Mateo County. Each groundwater well facility site would contain a groundwater production well, pump station, underground distribution piping, and utility connections. Some well facility sites would contain groundwater disinfection units and groundwater treatment facilities. Well facilities would connect to distribution systems for Daly City, San Bruno, Cal Water, and SFPUC. In addition, the Westlake Pump Station in Daly City may need to be upgraded and treatment facilities may need to be added to several well facility sites.

FINDING

This project may have a significant effect on the environment and an Environmental Impact Report is required. This determination is based upon the criteria of the State CEQA Guidelines, Sections 15063 (Initial Study), 15064 (Determining Significant Effect), and 15065 (Mandatory Findings of Significance), and for the reasons documented in the attached project description and description of potential environmental effects. (Documents are also available online at: http://www.sfgov.org/planning/mea.)

PUBLIC SCOPING PROCESS

Pursuant to the State of California Public Resources Code Section 21083.9 and CEQA Guidelines Section 15206, a public scoping meeting will be held to receive oral comments concerning the scope of the EIR at the following location, date, and time.



DATE: Thursday, July 9, 2009

6:15-7:00 p.m. Informational Session

7:00 p.m. Scoping meeting

LOCATION:

South San Francisco Municipal Services Building

Community Room

33 Arroyo Drive

South San Francisco, CA

Written comments will also be accepted at this meeting and until the close of business on **July 28, 2009**. Written comments should be sent to Bill Wycko, Environmental Review Officer, Regional Groundwater Storage and Recovery Project Scoping Comments, San Francisco Planning Department, 1650 Mission Street, Suite 400, San Francisco, CA 94103. They also may be submitted by fax to (415) 558-6409 or sent by email to diana.sokolove@sfgov.org.

If you work for a Responsible or Trustee Agency, we need to know the views of your agency regarding the scope and content of the environmental information that is germane to your agency's statutory responsibilities in connection with the proposed Project. Your agency may need to use the EIR when considering a permit or other approval for this proposed Project. Please include the name of a contact person in your agency.

Regional Groundwater Storage and Recovery Project

2008.1396E

~~Case No 2005.0164E~~

1.0 OVERVIEW AND BACKGROUND

The San Francisco Public Utilities Commission (SFPUC) is proposing the Regional Groundwater Storage and Recovery (GSR) Project (Project or proposed Project), which would be located in northern San Mateo County, California (see Figures 1, 2, and 3). To meet California Environmental Quality Act (CEQA) requirements, the San Francisco Planning Department's Major Environmental Analysis Division (MEA) will prepare and distribute an Environmental Impact Report (EIR) describing and analyzing the environmental effects of the proposed Project. This Notice of Preparation (NOP) provides a description of the Project background, a brief description of the proposed Project elements, and describes some of the proposed Project's potential environmental effects.

The purpose of the proposed Project is to further the use of the South Westside Groundwater Basin as an underground storage reservoir by storing water in the basin during wet periods for subsequent recapture during dry periods. This new dry-year water supply would be made available to the cities of Daly City and San Bruno, the California Water Company (Cal Water) in its South San Francisco service area (collectively designated as Partner Agencies) and SFPUC wholesale water customers.

SFPUC proposes to provide excess surface water when available to the Partner Agencies to be used by these agencies in lieu of pumping groundwater during normal and wet years. The Partner Agencies currently use groundwater as one of the sources of their drinking water supply. This supply would be partially replaced by surface water supplies from the SFPUC regional water system. The reduction of groundwater pumping by Partner Agencies would ultimately increase groundwater storage within the South Westside Groundwater Basin by up to 61,000 acre-feet[1] (AF) (approximately 20 billion gallons). Stored

[1] The SFPUC plans for an 8.5-year drought. Over this 8.5-year period, the SFPUC anticipates it will exercise its dry-year supplies after the first year of the drought. Therefore, the 61,000 AF of storage is assumed to be used over 7.5 years of the design drought, with wells operating at a maximum capacity of 7.2 MGD.

groundwater would be utilized by pumping new Project wells during periods of insufficient surface water supplies (i.e., dry years). As part of the proposed Project, SFPUC would create new groundwater production well facilities, which would be operated by either the Partner Agencies or SFPUC for pumping groundwater at a rate of up to 7.2 million gallons per day (MGD) during dry years. The proposed Project would help meet the water supply reliability needs of all SFPUC customers during dry years and may provide some increased level of regional operational flexibility to respond and restore service during unplanned outages.

The proposed Project is a component of the SFPUC's proposed Water System Improvement Program (WSIP) (see www.sfwater.org). The basic goals of the WSIP are to increase the reliability of the regional water system with respect to water quality, seismic response, delivery, and water supply to meet water delivery needs in the service area. A Program EIR (PEIR) for the WSIP was certified by the San Francisco Planning Commission, and the WSIP was adopted by the SFPUC on October 30, 2008. The PEIR addresses the potential environmental impacts of the WSIP facilities on a programmatic level and evaluates regional water supply alternatives. The proposed Project, which is the subject of this NOP, is one component of the WSIP[2]; implementation of this proposed Project would contribute to meeting the WSIP's overall goals and objectives.

For purposes of the WSIP PEIR, the SFPUC's regional water system facilities were subdivided into six regions: Hetch Hetchy, San Joaquin, Sunol Valley, Bay Division, Peninsula, and San Francisco. The proposed Project would occur in the San Francisco Region.

2.0 PROPOSED PROJECT FACILITIES

The proposed Project facilities would consist of new groundwater production well facilities within the South Westside Groundwater Basin (Basin); the facilities are designed to withdraw up to 7.2 MGD from the volume of stored groundwater directly resulting from Project-related reduced groundwater

[2] The Regional Groundwater Storage and Recovery Project was listed as the Conjunctive Use Project in the PEIR.

pumping in the Basin by Partner Agencies during normal and wet years. Up to 16 new groundwater well facilities would be constructed on 16 of the 19 potential sites in northern San Mateo County to supply the needed withdrawal capacity. Well facilities would be connected to Daly City, San Bruno, Cal Water, or SFPUC distribution systems. In addition, the existing Westlake Pump Station in Daly City may need to be modified and treatment facilities may need to be added.

Each groundwater well facility site would contain a groundwater production well, pump station, underground distribution piping, and utility connections. Each well facility would have a disinfection unit as required, unless it is near an existing disinfection unit that can accommodate the additional volume, in which case the well would be connected to the existing unit. Well facility sites where the groundwater may need treatment have been designed with appropriate treatment facilities.

3.0 ENVIRONMENTAL REVIEW PROCESS

As described above, the San Francisco Planning Commission certified the WSIP PEIR in October 2008. The PEIR addressed the potential environmental impacts of the WSIP facilities on a programmatic level and evaluated regional water supply alternatives. The PEIR is available on the San Francisco Planning Department website at www.sfgov.org/planning/mea.

The San Francisco Planning Department will prepare a project-specific EIR to evaluate the environmental effects of the proposed Project. The EIR will be prepared in compliance with the CEQA Guidelines Section 15161 and will address project-specific construction and operational impacts.

The first step in the environmental review process is the formal public scoping process, for which this NOP has been prepared. Following the public scoping period, a Draft EIR will be prepared and circulated for a 45-day public review period. Public comments on the Draft EIR will be accepted in writing during the review period or verbally at a formal public hearing to be held by the San Francisco Planning Commission. The San Francisco Planning Department then will prepare written responses to comments on environmental issues raised during the public review period, and a Response to Comments document will be prepared. That document will be considered by the San Francisco Planning

Commission, along with the Draft EIR and any revisions to the draft based on the response to comments, for certification as a Final EIR.

4.0 PUBLIC SCOPING MEETING

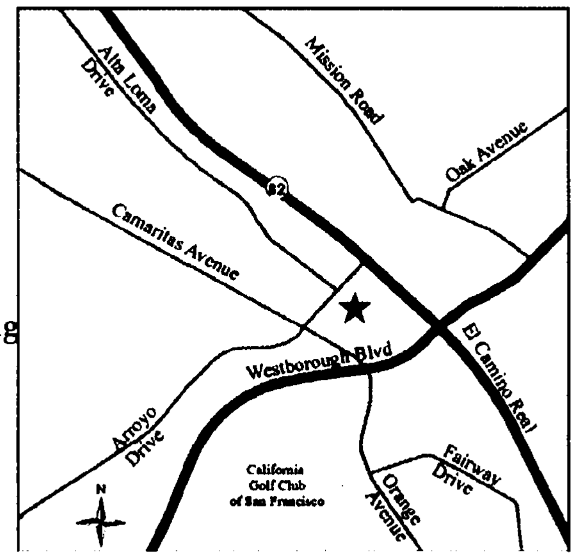
The San Francisco Planning Department will hold a public scoping meeting at the following location, date, and time.

DATE: Thursday, July 9, 2009

6:15-7:00 p.m. Informational Session

7:00 p.m. Scoping meeting

LOCATION:
South San Francisco Municipal Services Building
Community Room
33 Arroyo Drive
South San Francisco, CA



The purpose of this meeting is to assist the Planning Department with its review of the proposed scope and content of the EIR as summarized in this NOP. The public will be given the opportunity to provide comment for consideration. The San Francisco Planning Department also will accept written comments on the scope of the EIR at the meeting or by mail, email, or fax until close of business (5:00 p.m.) on **July 28, 2009**. Written comments may be submitted by mail to the San Francisco Planning Department, Attn: Bill Wycko, Environmental Review Officer, Regional Groundwater Storage and Recovery Project Scoping Comments, 1650 Mission Street, Suite 400, San Francisco, CA 94103. They also may be submitted by fax to (415) 558-6409, or sent by email to diana.sokolove@sfgov.org.

5.0 PROJECT DESCRIPTION

5.1 Project Location

The proposed Project is located in the South Westside Groundwater Basin in San Mateo County, and the proposed facilities will be constructed in northern San Mateo County as shown in Figures 1, 2, and 3. The South Westside Groundwater Basin is located in San Mateo County within the larger Westside Groundwater Basin[3], which underlies both San Francisco and San Mateo counties. The Project is also located within the water service areas for the cities of Daly City, San Bruno, and Millbrae and within the Cal Water service area, which includes portions of South San Francisco, Colma, and unincorporated San Mateo County.

Groundwater well facilities would be constructed and operated at up to 16 locations in the cities of Colma, Daly City, South San Francisco, San Bruno, Millbrae, and unincorporated San Mateo County (see Figures 1, 2, and 3). Well facilities would be connected to existing water distribution pipelines owned by Daly City, San Bruno, Cal Water, and SFPUC. The Project also includes an upgrade of the existing Westlake Pump Station in Daly City to serve the proposed new well facility sites.

5.2 Project Objectives

The proposed Project is a regional groundwater storage and recovery project that is part of the SFPUC's WSIP. The overall goals of the WSIP for the regional water system are to maintain high-quality water; reduce vulnerability to earthquakes; increase water delivery reliability; meet customer water supply needs; enhance sustainability; and achieve a cost-effective, fully operational system. The proposed Project's primary contribution to the WSIP goals is its ability to meet the water supply needs of SFPUC customers during drought years. In addition,

---

[3] The Westside Groundwater Basin extends from western San Francisco south into San Mateo County. The Basin has an area of approximately 40 square miles and underlies Daly City, Colma, South San Francisco, San Bruno, Millbrae, and Burlingame. The Westside Groundwater Basin has been administratively divided at the San Francisco County-San Mateo County line. This is a political boundary, not a physical boundary. The portion of the basin that lies within San Francisco County is referred to as the North Westside Groundwater Basin. The portion of the basin that lies within San Mateo County is referred to as the South Westside Groundwater Basin. The Project would occur solely within the South Westside Groundwater Basin.

the Project may provide some increased level of regional operational flexibility to respond and restore service under unplanned outages.

The specific objectives of the proposed Project are to:

- Cooperatively manage the South Westside Groundwater Basin through the coordinated use of SFPUC surface water and the groundwater pumped by the Partner Agencies;
- Provide increased SFPUC surface water to the Partner Agencies in normal and wet years, resulting in a reduction of groundwater pumping by these agencies and an increase in groundwater storage in the South Westside Groundwater Basin;
- Increase the pumping capacity from the South Westside Groundwater Basin by up to 7.2 MGD to supply water during dry years and emergencies; and
- Provide a new dry-year groundwater supply for SFPUC customers and increase water supply reliability during the 8½-year design drought cycle.

5.3 Proposed Project

The proposed Project is a groundwater storage and recovery project, which includes the operation of new groundwater production wells and associated distribution and treatment facilities. This section includes a description of these proposed Project components.

5.3.1 Groundwater Storage and Recovery

The Partner Agencies currently supply potable water to their customers through a combination of groundwater from the South Westside Groundwater Basin and purchase of SFPUC surface water. The proposed Project would provide additional SFPUC surface water to the Partner Agencies during normal and wet years when sufficient surface water supplies are available. The Partner Agencies would reduce their groundwater pumping by a comparable amount and allow the groundwater basin to recharge naturally during these periods.

Figure 4 illustrates the increase in groundwater storage expected from a reduction in pumping during normal and wet years, as well the decrease in groundwater storage projected from an increase in pumping during dry years.

During normal and wet years, the volume of groundwater in the South Westside Groundwater Basin would naturally increase due to the reduced groundwater pumping, eventually reaching an increased storage volume of up to 61,000 AF. During dry or drought years, the Partner Agencies and SFPUC would pump previously stored groundwater. This new dry-year water supply would be made available to both the Partner Agencies and SFPUC wholesale customers under the terms of the Shortage Allocation Plan between the SFPUC and its wholesale customers[4]. A groundwater storage and recovery agreement would be negotiated by and between the SFPUC and Partner Agencies for groundwater and surface water management. Specifically, the agreement would cover water accounting; ownership principles; and operation, maintenance and replacement of facilities.

5.3.2 *Production Wells and Associated Facilities*

The proposed Project includes new groundwater production well facilities within the South Westside Groundwater Basin to withdraw the increased volume of stored groundwater at a rate of 7.2 MGD. Up to 16 new groundwater well facilities would be constructed on 16 of the 19 potential sites in northern San Mateo County. Of the 19 sites, 5 well facilities would connect to Daly City's distribution system, 3 well facilities would connect to San Bruno's distribution system, 4 well facilities would connect to Cal Water's distribution system, and 7 well facilities would connect to the SFPUC distribution system. In addition, the Westlake Pump Station in Daly City may be expanded and additional treatment facilities added.

Each groundwater well facility site would contain a groundwater production well, a pump station, underground distribution piping, and

---

[4] The Shortage Allocation Plan identified a water allocation method to be used to determine the share of water for wholesale customers during shortages caused by drought.

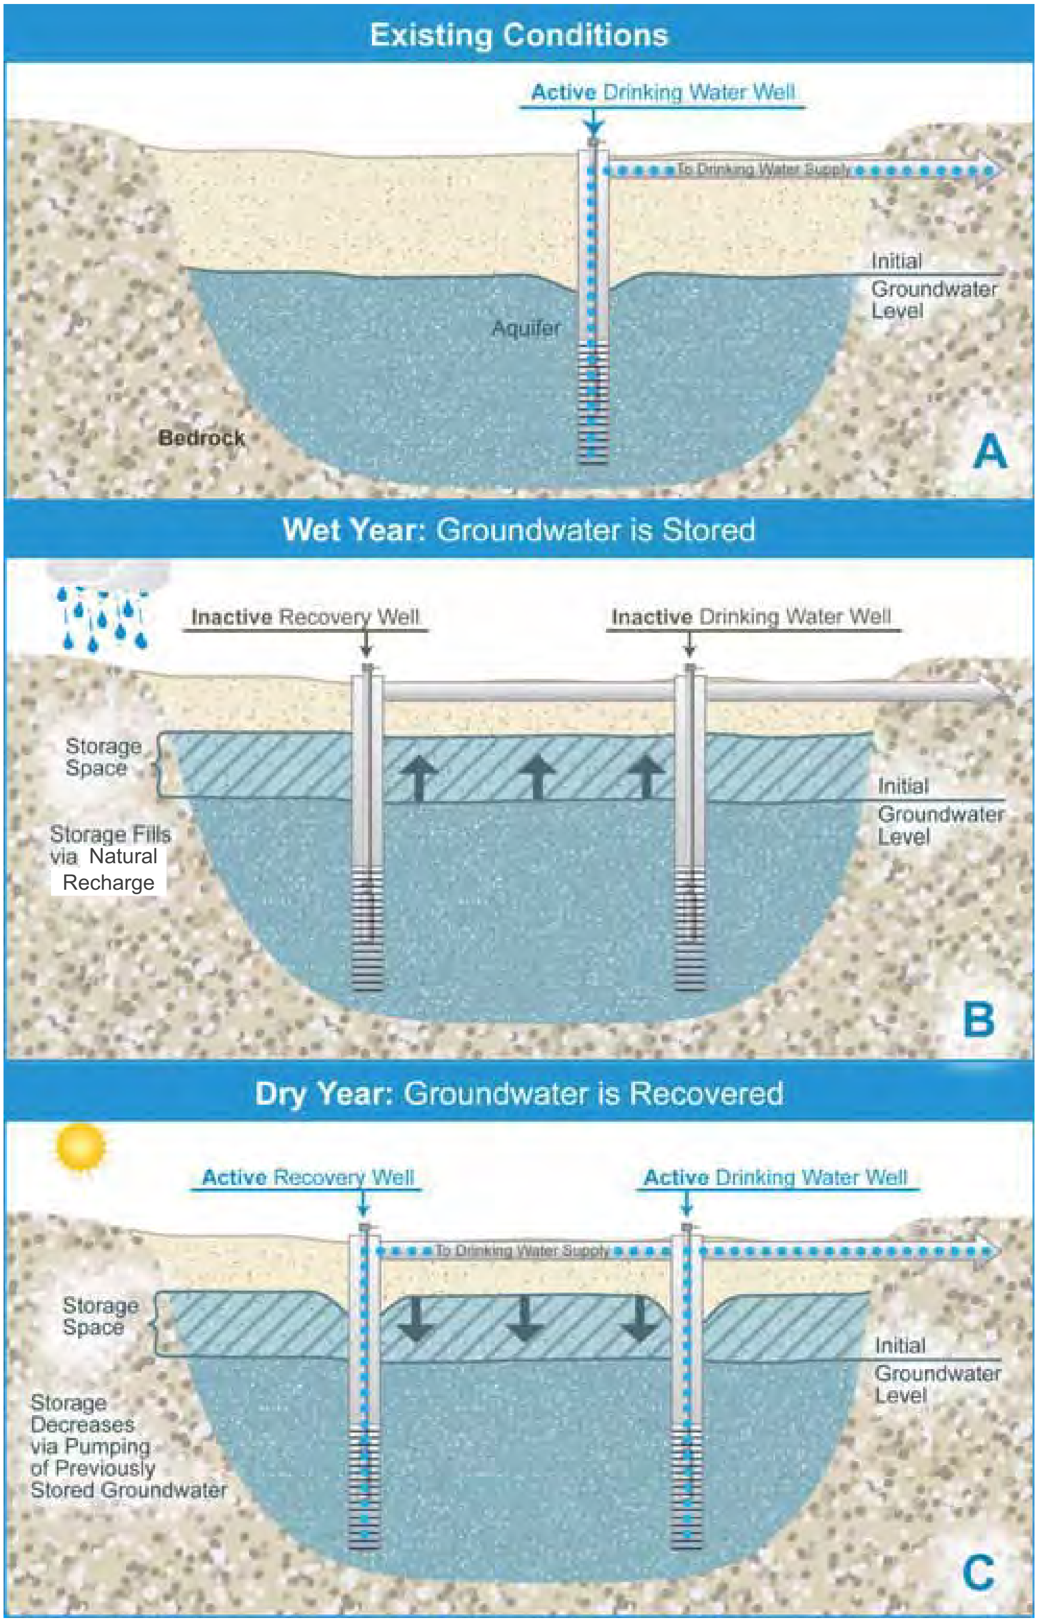


Figure (A) reflects the existing groundwater conditions, showing available storage space above the aquifer. In (B) the upward arrows represent the filling of the storage space with groundwater during wet years; in (C) the downward arrows represent the decline in stored water during dry years. The "Drinking Water Wells" represent the existing wells operated by the Cities of San Bruno and Daly City and California Water Service Company. The "Recovery Wells" represent the new wells that are proposed as part of the Project.

Groundwater Storage and Recovery

Regional Groundwater Storage and Recovery Project

Figure 4

utility connections. Each well facility also would have a disinfection unit, unless it is located near an existing disinfection unit that can accommodate the additional volume, in which case the well would be connected to the existing unit. Well facility sites where the groundwater may need treatment have been designed with appropriate treatment facilities (e.g., disinfection and manganese treatment). The facilities and the nature, extent and anticipated duration of construction activities are described further below.

Prior to confirming the final selected sites and full development of the groundwater well facilities, monitoring wells and test wells may be installed at the well facility sites to gather information about local groundwater characteristics and to determine the technical feasibility of each of the sites to produce sufficient volumes and quality of water for operation of a groundwater production well. If selected, sites would be converted from test wells to permanent production wells; pumps would be added, well enclosures would be built (fencing or building), disinfection units and treatment facilities would be constructed as needed, and utility and distribution pipelines would be installed.

A list of the 19 potential well facility sites and pump station upgrade is provided in Table 1.

TABLE 1
Well Facility Locations

Site ID[a]	Site Name	Location
1	Lake Merced Golf Course	Daly City
2	Park Plaza Meter	Daly City

PS	Westlake Pump Station Upgrade	Daly City

a. The EIR will evaluate the environmental effects of the development of all 19 well facility sites, even though a maximum of 16 well facilities would be constructed.

Well Station Design

The SFPUC has considered institutional, regulatory, operational, maintenance, and technical information in the design of the well stations. Three well station types are included in the proposed Project:

- Type 1 - well only, building or fenced enclosure;
- Type 2 - well plus chemical treatment building; and
- Type 3 - well plus chemical treatment and filtration building.

Site-specific well station design characteristics are listed in Table 2 and described in detail below. These characteristics include proposed building type, pump type, water distribution system connection point, groundwater disinfection location, and the method that would be used to achieve agency-specific water quality goals (i.e., blending with surface water or treatment).

TABLE 2

Site-Specific Well Station Characteristics

Site ID	Site Description	Well Station Type[a]	Pump Type	Connection Point	Alternate Connection Point	Disinfection Location	Method for Achieving Water Quality Goals
1	Lake Merced Golf Club	Type 2	Above-ground	SFPUC San Andreas Pipeline #2	Daly City	At site	Blending[b]
2	Park Plaza Meter	Type 1 with fenced enclosure	Submersible	Daly City	SFPUC Sunset Supply	Westlake Pump Station	Blending
3	Ben Franklin Intermediate School	Type 1 with fenced enclosure	Submersible	Daly City	SFPUC Sunset Supply	Westlake Pump Station	Blending
4	Garden Village Elementary School	Type 1 with fenced enclosure	Submersible	Daly City	SFPUC Sunset Supply	Westlake Pump Station	Blending or iron/manganese treatment
5	Right-of-Way at Serra Bowl	Type 2	Above-ground	Daly City	Cal Water	At site	Blending or iron/manganese treatment
6	Right-of-Way at Colma BART	Type 2	Above-ground	Cal Water	SFPUC Pipeline	At site	Blending or iron/manganese treatment
7	Right-of-Way at Colma Boulevard	Type 2	Above-ground	Cal Water	SFPUC Pipeline	At site	Blending or iron/manganese treatment
8	Right-of-Way at Serramonte Boulevard	Type 2	Above-ground	Cal Water	SFPUC Pipeline	At site	Blending or iron/manganese treatment
8a	Standard Plumbing Supply	Type 2	Above-ground	Cal Water	SFPUC	At site	Blending
9	Treasure Island Trailer Court	Type 2	Above-ground	SFPUC Sunset Supply Pipeline	None	At site	Blending

TABLE 2
Site-Specific Well Station Characteristics

Site ID	Site Description	Well Station Type[a]	Pump Type	Connection Point	Alternate Connection Point	Disinfection Location	Method for Achieving Water Quality Goals
10	Right-of-Way at Hickey Boulevard	Type 2	Above-ground	Daly City	SFPUC San Andreas #2	At site	Blending
10a	Alta Loma Drive	Type 2	Above-ground	SFPUC San Andreas Pipeline #2	Cal Water	At site	Blending
11	SSF Main Area	Type 2	Above-ground	SFPUC Sunset Supply Pipeline	Cal Water	At site	Blending
12	Funeral Home	Type 2	Above-ground	SFPUC Sunset Supply Pipeline	Cal Water or other SFPUC pipeline	At site	Blending
12a	Funeral Home	Type 2	Above-ground	SFPUC Sunset Supply Pipeline	Cal Water or other SFPUC pipeline	At site	Blending
13	SSF Linear Park	Type 3	Above-ground	San Bruno	Cal Water, SFPUC, or other San Bruno	At site	Blending or iron/manganese treatment
14	Golden Gate National Cemetery	Type 1 with building enclosure	Above-ground	San Bruno	SFPUC pipeline	At site	Blending or iron/manganese treatment
15	Golden Gate National Cemetery	Type 3	Above-ground	San Bruno	SFPUC pipeline	At site	Blending or iron/manganese treatment
16	Millbrae Corp Yard	Type 2	Above-ground	SFPUC Crystal Springs Pipeline #2	None	At site	Blending

a. Type 1 is Well Only; Type 2 is Well plus Chemical Treatment Building; Type 3 is Well plus Chemical Treatment and Filtration Building; see text below for further description of conceptual layouts.

b. Blending is the mixing of groundwater with other potable supply water

Buildings would be about 15 feet tall and constructed of concrete block. Acoustical louvers for noise reduction would be used. The buildings would be painted in neutral colors with anti-graffiti coating.

It is anticipated that all outdoor site lighting would be activated by motion-controlled sensors, with manual switching available for as-needed night operations. Facilities would be designed to meet California's energy efficiency standards outlined in Title 24 of the California Code of Regulations and use recycled materials to the extent possible.

Type 1 Conceptual Layout: Well-Only. The conceptual layout for the "well-only" type includes an approximately 40-foot by 20-foot building or fenced enclosure to house the wellhead, pump, piping, and associated electrical and control equipment.

Type 2 Conceptual Layout: Well plus Chemical Treatment. The conceptual layout for the "well with chemical treatment" type would consist of a 40-foot by 20-foot building to house the wellhead, pump, pipeline, and associated electrical and control equipment, plus an approximately 15-foot by 15-foot building extension for chemical storage and handling. Space would be provided onsite for disinfection, pH adjustment, and fluoride addition if needed.

Type 3 Conceptual Layout: Well plus Chemical Treatment and Filtration. The conceptual layout for the "well with chemical treatment and filtration" type would be similar to Type 2 but with the addition of a filtration system. The building dimensions would be approximately 25 feet by 80 feet. Filtration would be located only at well facilities that require manganese and/or iron removal. This well station type would be larger than the other types to provide space for the wellhead, treatment facilities, and filtration vessels. The filtration system consists of a series of vertical pressure vessels. The number and size of the pressure vessels would depend on the well yield and the number of wells connected to the filtration system. The backwash water from the system would connect to a nearby sanitary sewer. It is anticipated that filters would be backwashed, on average, once a day for 4 minutes.

Well Pumps

Each well facility site would contain either a submersible or above-ground pump. The selection of the pump type is based on the preference of the Partner Agency responsible for well operation. In most cases, the wells would be equipped with above-ground pumps. In comparison to submersible motors, above-ground motors are more efficient, have a longer service life, are more durable in cases where variable frequency drives are required, and are more accessible and thus easier to maintain. In cases where noise, visibility, or lack of space is an issue, submersible pumps would be used. Submersible motors are quieter to operate, but more difficult to maintain, because maintenance requires the removal of the entire pump assembly. Any wells that are in fenced enclosures (i.e., without buildings) have been designated for submersible pumps.

Utility and Distribution Piping

Underground piping would connect the wells to the local distribution systems or SFPUC water distribution system. In addition, underground piping would connect well facilities to the storm drain system and/or the sanitary sewer system to allow discharge of the initial flush of water. Chloraminated water would be de-chlorinated or sent to the local sanitary sewer system. Backwash from the manganese treatment facilities would also be sent to the local sanitary sewer system. The piping for all selected sites would consist of a total of approximately 4,600 feet of 6-inch pipe and 12,500 feet of 8-inch pipe. In general, the pipeline route would be excavated to a depth of 6 feet. The maximum width of the pipeline work area (including the trenches) would be 20 feet. The pipelines would be constructed using conventional open-cut trenching techniques. Above or underground electrical lines would also be installed from the groundwater well facilities to the nearest power source (PG&E facilities). The dimension of the trenches for the underground electrical lines would be smaller than those of the water pipelines.

Westlake Pump Station Upgrade

Upgrades to the Westlake Pump Station may be necessary to serve the well stations at Sites 2, 3 and 4. The upgrades would include new chemical storage tanks, replaced or upgraded chemical metering pumps, a resized transformer, and up to three new booster pumps to deliver the additional water into the distribution system.

5.3.3 *Construction Methods*

Monitoring Wells, Geotechnical Borings, and Test Wells

Prior to the selection and full development of the groundwater production well sites, monitoring wells and test wells may be installed and geotechnical borings may be drilled at the well facility sites to gather information about local groundwater characteristics and to determine the technical feasibility of each of the sites to produce sufficient volumes and quality of water for operation of a groundwater production well. Depending upon the results of the testing, well facility sites would be selected, and test wells converted to permanent production wells, which would consist of full development of the well facility site to include the addition of pumps to the wells, the addition of enclosures around the well, installation of disinfection units and treatment facilities as needed, and installation of utilities and distribution pipelines.

In the event that additional monitoring or test wells are needed, the selected site would need to be cleared of vegetation and graded for installation and drilling of the borehole. For monitoring wells, a borehole would be drilled to a depth of approximately 750 feet below ground. For test wells, one steel casing would be installed to a depth of approximately 50 feet, with a borehole drilled to a depth of approximately 550 to 700 feet. Equipment used for well drilling and construction would include a mounted drill rig on a support truck, pump and pick up trucks or trailers and similar equipment. Construction of a monitoring well would be completed in approximately three weeks, with construction activities occurring between 8:00 AM and 7:00 PM Monday through Friday only. Construction and testing of test wells would require approximately 4 weeks. Drilling would extend for about a week both during the day and night. If the results of the test wells were favorable and the wells were selected as permanent production well sites, then development of production well facilities would occur, as described below.

Additional geotechnical borings may be required and would be drilled to a depth of approximately 50 feet below ground surface (deeper if fill or soft soil is encountered). A boring would be completed in approximately two days. Drilling activities would occur between 8:00 AM and 7:00 PM Monday through Friday only.

Construction of Well Station Facilities

Each well facility site would include a construction staging area; some sites may have two optional locations for staging areas. The minimum size of the staging area would be 1,500 square feet. Staging areas would be fenced. Any temporary spoils (excavated material) storage would occur inside the staging areas.

Construction of facilities at the well sites would require site clearing and grubbing. Site excavation and grading would be minor, with grading to a maximum depth of 5 feet for the building foundation (if the well facility includes a building) and utilities underneath the building. After the foundation and utilities connections are constructed, the remainder of the building would be constructed and the well pump and other equipment installed, as needed. No significant near-surface groundwater is expected at any site; therefore dewatering for construction of project facilities is not anticipated. Diesel generators with self-contained fuel tanks may be used during construction. Construction equipment is expected to include: a front end loader, backhoe/excavator, fork lift, telescopic crane, cement mixer, concrete pump truck, compactor, hauling trucks, pump-setting rig, and arc welder.

It is estimated that during the peak construction period, the maximum number of construction workers at any one site would be 15.

Construction of Distribution and Utility Connections

In general, the pipeline routes would be excavated up to a depth of 6 feet. The width of pipeline construction zones would be generally 20 feet, and the width of the electrical connection construction zones would be less than 20 feet. The pipelines would be constructed using conventional open-cut trenching techniques. Construction equipment is expected to include: an excavator, front-end loader, hauling trucks, compactor, asphalt trucks, and arc welder. Diesel generators with self-contained fuel tanks may be used during construction. At some sites, pipeline excavation would generate excess soil (called spoils) that would be reused onsite (for engineering fill) or disposed of at a Class III non-hazardous waste disposal site. After pipeline placement, the trenched area would be restored to its original condition.

5.3.4 *Operation and Maintenance*

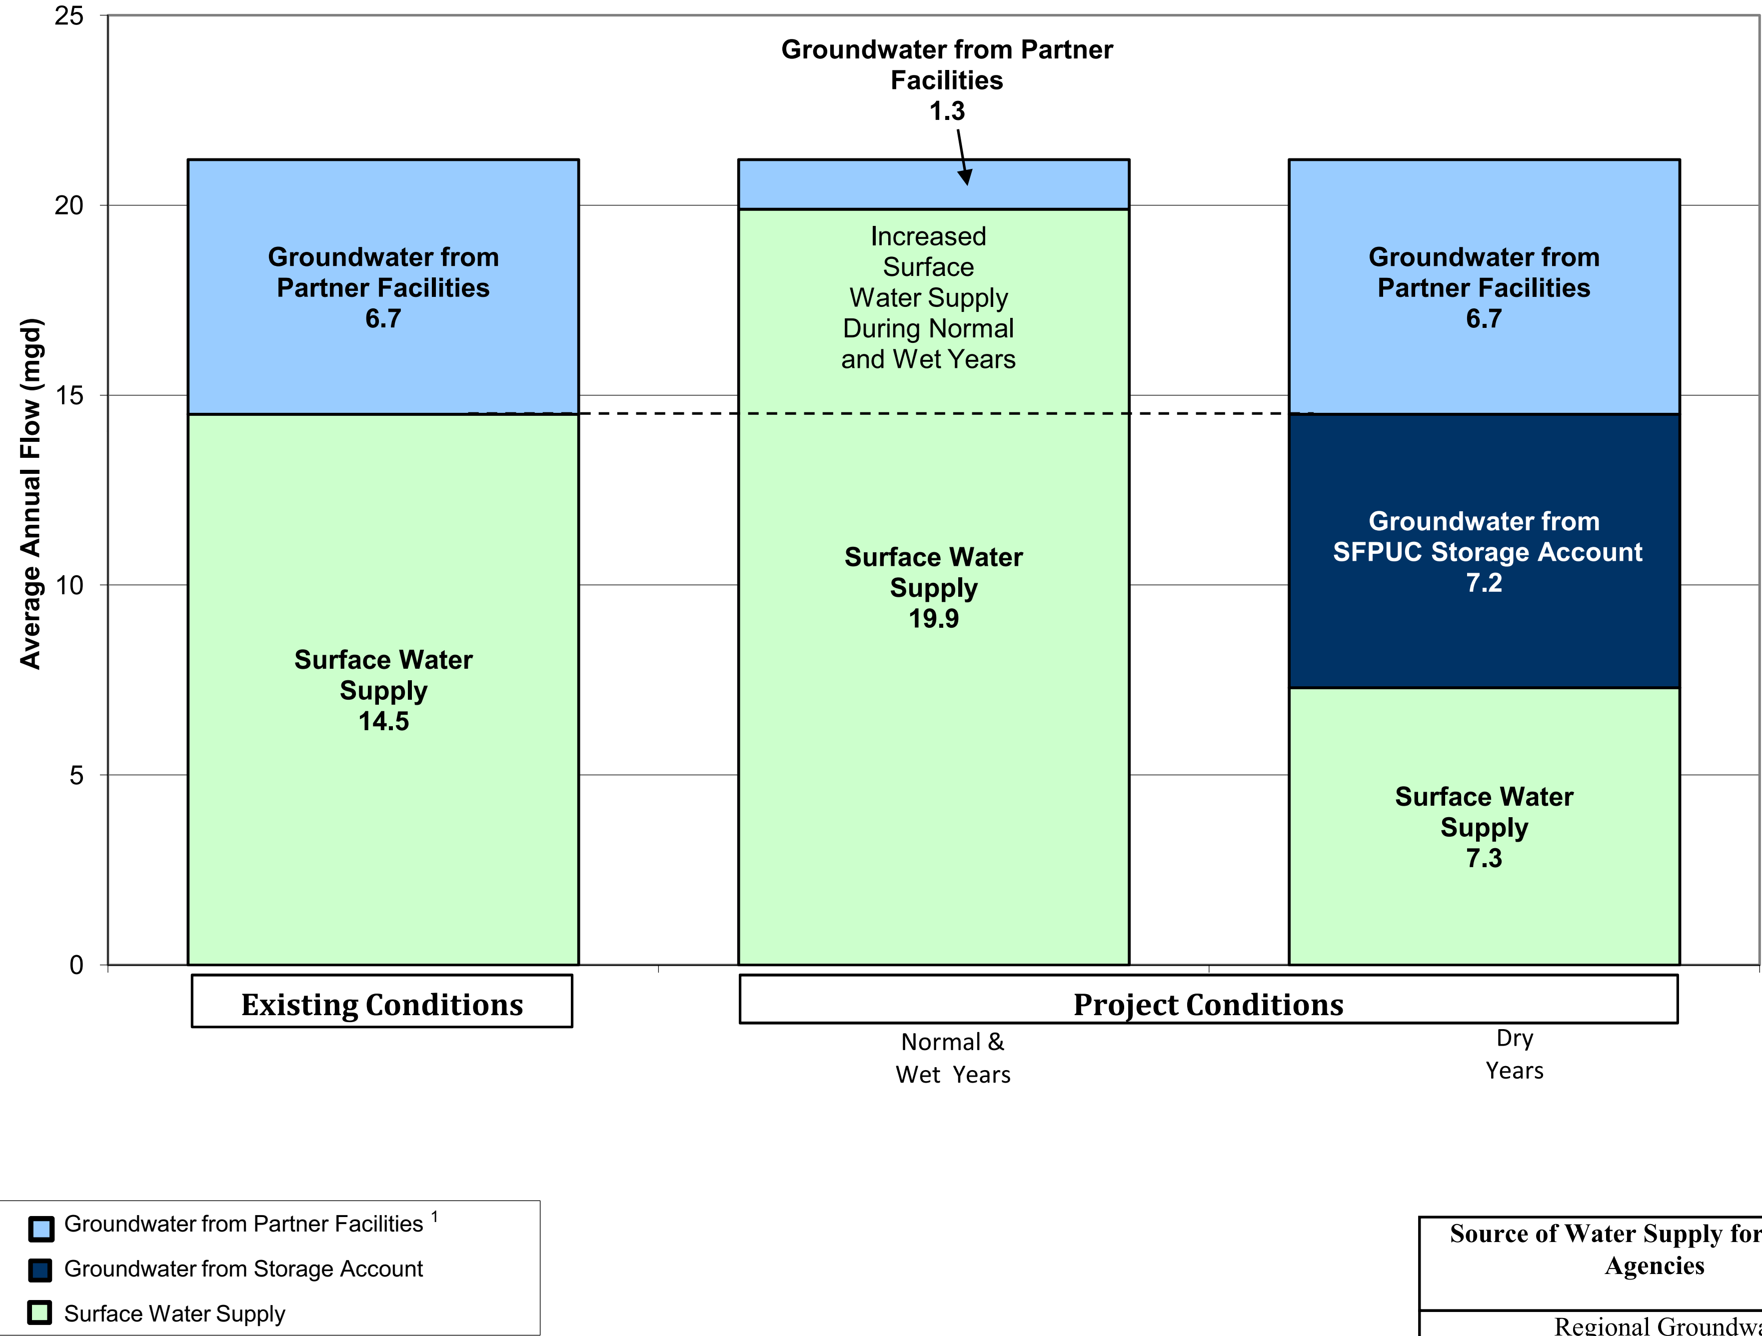
Project operations would be designed to allow natural recharge of the South Westside Groundwater Basin through reduced Partner Agency groundwater pumping, to provide up to 61,000 AF of increased groundwater in storage to be used by the SFPUC and Partner Agencies during drought conditions.

Figure 5 illustrates how the Project would change the source of water supply for the Partner Agencies. During normal and wet years, the portion of water supply coming from SFPUC surface water would increase compared to the existing condition. During dry years, the portion of water supply coming from groundwater would increase compared to the existing condition. For SFPUC wholesale water customers, the source of water supply would not change during normal and wet years; but the portion of groundwater delivered to some SFPUC customers would increase during dry years, compared to existing conditions.

An accounting of additional storage volumes (called the SFPUC Storage Account) would track the amount of water that has been stored during the normal and wet years and the amount of water pumped during dry years. The specific volumes shown in Figure 5 are based on historic rainfall and hydrology (MWH, 2007), but actual volumes in any given year would vary depending on several factors, including: 1) the final location and capacity of the project well facilities, 2) the availability of additional stored water in the SFPUC Storage Account, and 3) direction from the Operating Committee[5] regarding which wells should be used.

---

[5] It is expected that a Project agreement by and between SFPUC and the Partner Agencies would establish an Operating Committee. The role of the Operating Committee would be to monitor and track the SFPUC Storage Account, including any losses from the system, and establish pumping schedules for the project wells.



[1] Partner facilities are operated by City of Daly City, City of San Bruno, and Cal Water.

Source of Water Supply for Partner Agencies

Regional Groundwater Storage and Recovery Project

Figure 5

During normal and wet years, the proposed groundwater well facilities would be operated by SFPUC or by Partner Agencies only periodically for maintenance purposes. During dry years, the proposed groundwater well facilities would be operated by SFPUC or by Partner Agencies for additional water supply.

All well stations would be unmanned, but subject to remote monitoring and operation by the Partner Agency or SFPUC who would operate the well facility. Each well station would be visited daily when wells are operating for routine equipment checks, lasting approximately 30 minutes each. During normal and wet years, wells would be visited on a weekly basis, would be normally off, but regular exercising would be conducted. Longer term maintenance would include removal and repair or replacement of pumps, valves, and other equipment. Production wells may require redevelopment and/or rehabilitation on an infrequent basis.

6.0 PERMITS AND APPROVALS REQUIRED

The SFPUC may be required to obtain the following permits and approvals for Project construction and operation:

- Section 404 Permit from the U.S. Army Corps of Engineers (USACE) if the Project affects jurisdictional wetlands or waters of the U.S.
- U.S. Department of Veterans Affairs approval and National Environmental Policy Act (NEPA) review for Sites 14 and 15 at the Golden Gate National Cemetery.
- U.S. Fish & Wildlife Service Section 7 consultation under the federal Endangered Species Act, if the Project affects threatened or endangered species or their habitat.
- Review by the Advisory Council on Historic Preservation may be required if the Project affects properties listed on or eligible for the National Register of Historic Places.
- Permit amendments and approval of well construction and operation from the California Department of Public Health, Water Supply Division.
- Section 1602 Lake and Streambed Alteration Agreement from the California Department of Fish and Game if the Project could affect streambeds under California jurisdiction.
- Section 2081/2080.1 Incidental Take Permit from the California Department of Fish and Game if a "take" (to hunt, pursue, catch, capture,

or kill, or attempt the same) could occur to state-listed species as a result of the Project.

- California Department of Fish and Game Memorandum of Agreement if needed to ensure no effect to fully protected species.
- Preparation of a California Department of Toxic Substances Control Contaminated Soil Treatment Work Plan (required only if contaminated soil is encountered during construction).
- San Francisco Bay Regional Water Quality Control Board Discharge permits, if required, for emergency and/or maintenance water discharges, and for "overboard" pumping of well waters.
- San Francisco Bay Regional Water Quality Control Board Section 401 Certification, the state certification of the federal Section 404 Wetlands Permit.
- California Department of Transportation Encroachment permits to cross State roadways and Interstate Highways.
- State Water Resources Control Board Stormwater General Permit and Stormwater Pollution Prevention Plan, if more than one acre of land is disturbed.
- Bay Area Air Quality Management District permit for stationary equipment that may generate air pollutants (e.g., generators).
- EIR certification by the San Francisco Planning Commission.
- Board of Supervisors approval may be needed for funding appropriation or property rights acquisition.
- SFPUC approval, adoption of CEQA findings and mitigation monitoring and reporting program (MMRP).
- Adoption of CEQA findings and MMRP by local City Councils or Boards of Supervisors.
- San Francisco Historic Preservation Commission review of local, state and national landmarks and historical landscapes.
- Determination of Project consistency with park use by local Recreation and Park Commissions and approval of use of property under their jurisdiction.
- Approval of local Unified School District(s) for use of property under their jurisdiction.
- Approval of exterior design of proposed facilities on SFPUC property or right-of-way by the San Francisco Arts Commission.
- Agreements with Partner Agencies.
- Local Department(s) of Public Health approval of well construction and operation permits in accordance with California Department of Water Resources Standards.

- Local Department(s) of Public Health approval of Certified Unified Program Agencies (CUPA)/Hazardous Materials Business Plan for Project operations.
- Local Department(s) of Public Works approval of excavation permits, encroachment permits, and temporary occupancy permits for street space.
- Bay Area Rapid Transit (BART) encroachment permits to cross existing BART system.

7.0 PROPERTY RIGHTS ACQUISITION

Several types of property rights would be needed for Project construction and operation, as shown in Table 3. The process for acquiring right-of-way involves the preparation of deed and appraisal map, an appraisal of fair market value, negotiations with property owners, and condemnation (if necessary).

TABLE 3
Property Rights Proposed for Acquisition

Property Acquisition Type	Rights
Access Easement	Temporary or permanent rights to enter or cross another property
Pipeline Easement	Rights to install and maintain a pipeline over or across another property
Fee Acquisition	Purchase of all the property rights, land, improvements (if any), etc.
Encroachment Permit	Rights to encroach across a publicly-owned street or highway for pipeline or other purposes

Of the 19 potential well sites, 12 sites are on SFPUC fee-owned land or within SFPUC right-of-way. The other seven well sites are on other public and private parcels which would require an acquisition of property use rights for the well(s), connecting pipelines, and/or access. Lastly, several sites have lengthy connecting pipeline requirements that would most likely be constructed on a combination of public and private parcels.

8.0 CONSTRUCTION SCHEDULE

The proposed Project schedule expected at the time of this NOP includes construction of permanent well facilities and pipeline connections from April 2012 through approximately May 2014.

9.0 ENVIRONMENTAL ANALYSIS

9.1 Environmental Issues to be Addressed in the EIR

The EIR will address all environmental issue areas required under CEQA. The EIR will address environmental impacts of the proposed Project due to construction and operation activities and will propose mitigation measures for impacts considered to be significant. The following sections describe the anticipated environmental issues that will be addressed by the EIR.

9.1.1 Land Use and Visual Quality

Construction and operation of the proposed Project could affect land uses and visual quality of the Project sites and surrounding areas. Potential impacts to be evaluated in the EIR include:

- Temporary and permanent disruption or displacement of existing land uses during construction including construction impacts on such sensitive land uses as schools, residences and funeral homes, and the potential temporary closure of a portion of South San Francisco Linear Park to the public.
- Impacts on scenic vistas or visual character, including potential impacts on the visual character of Golden Gate National Cemetery, Woodlawn Cemetery, Greenlawn Memorial Park, and Lake Merced Golf Club.

9.1.2 *Geology, Soils and Seismicity*

Construction and operation of new well facilities and below-ground distribution pipelines and electrical power lines could result in site-specific impacts on or from local geology and soils conditions. Potential impacts to be evaluated in the EIR include:

- Seismic hazards and/or increased exposure of people and structures to seismic hazards, including impacts from ground-shaking in the event of an earthquake on the San Andreas fault or other Bay Area fault.
- Increased exposure of people or structures to geologic hazards (such as liquefaction, poor soil conditions, or unstable slopes) from construction in geologic hazard zones.
- Soil erosion potential from construction activities.
- Potential land subsidence from drawdown of the groundwater aquifer.

9.1.3 *Hydrology and Water Quality*

Construction and operation of the Project could affect surface water quality and could affect groundwater levels and quality in the Project area and in the South Westside Groundwater Basin as a whole. Potential impacts to be evaluated include:

- Changes in local groundwater quality and levels within the South Westside Groundwater Basin as a whole.
- Changes in drinking water quality due to use of treated groundwater.
- Alteration of drainage patterns and increase in stormwater flows due to increase in the amount of impervious surfaces.
- Degradation of surface water quality as a result of erosion and sedimentation, hazardous materials release during construction, and construction dewatering discharges.

9.1.4 *Biological Resources*

The proposed Project could result in a permanent loss of wetlands and sensitive habitats and could directly impact special-status wildlife and plant species. Temporary impacts to biological resources could result from proximity to construction activities, including noise, vibration, and dust. Potential impacts to be evaluated include:

- Impacts on wetlands and aquatic resources.
- Impacts on sensitive wildlife habitats and protected/heritage trees.
- Impacts on special-status wildlife and plant species – direct mortality and/or habitat effects.
- Conflicts with adopted conservation plans or other approved biological resources plans.

9.1.5 *Cultural Resources*

The proposed Project could affect archaeological, historical, or paleontological resources through ground-disturbing activities during construction, or by introducing new facilities that compromise the historic integrity of historic buildings or landscapes. Potential impacts to be evaluated include:

- Impacts on archaeological and paleontological resources.
- Impacts on the historical significance of a historic district, contributor to a historic district, or historic landscape. Of particular focus will be the proposed well facilities on 1920s Lake Merced Golf Club; the turn of the century Woodlawn Cemetery, the Cypress Lawn Cemetery, and the Golden Gate National Cemetery.
- Impacts on Native American cultural resources.

9.1.6 *Traffic, Transportation and Circulation*

Construction could have temporary impacts on traffic volumes, traffic safety, and parking in the vicinity of the well facility sites and at the Westlake Pump Station. Potential impacts to be evaluated EIR include:

- Temporary reduction in roadway capacity and increased traffic delays, including impacts from short-term closure of one parking and/or traffic lane. Impaired access to adjacent roadways and land uses.
- Temporary displacement of on- or off-street parking.
- Increased traffic safety hazards during construction.
- Long-term traffic increases during facility operation.

9.1.7 Noise and Vibration

Construction noise and vibration impacts from the proposed Project would be associated with facility construction activities, and therefore, would be temporary and short-term. Operation of the proposed pumps and treatment facilities could create permanent noise impacts. Potential impacts to be evaluated include:

- Impacts of construction noise and vibration on sensitive receptors in the vicinity of Project construction sites, especially such sensitive land uses as schools, health care facilities, cemeteries, funeral homes, and churches.
- Noise impacts from groundwater well station operation, including pumps and groundwater treatment facilities.

9.1.8 Recreational Resources

Construction could temporarily disrupt recreational uses in the vicinity of the well facility sites as a result of noise, dust, and temporary access restrictions. The EIR will evaluate the impact of the Project on recreational resources. Potential impacts to be evaluated include:

- Temporary and permanent impacts on recreational facilities, including but not limited to Lake Merced Golf Club and Linear Park in South San Francisco.

9.1.9 Other Environmental Issues

Other environmental issues that will be evaluated in the EIR include the Project's potential impacts on air quality and greenhouse gas emissions; public services and utilities, including the Project's beneficial effect on water supply; agricultural resources; hazards, including the potential hazards from chemical storage at the well sites; and energy resources.

The EIR also will evaluate any potential growth-inducing impacts that could result from implementation of the Project. The EIR also will address whether the Project could result in impacts that would be significant when combined with the impacts of other SFPUC or non-SFPUC projects occurring in the same geographic area as the Project and at the same time.

9.2 Alternatives

CEQA requires that an EIR evaluate a reasonable range of feasible alternatives to the project, or to the location of the project, that would attain most of the basic project objectives but that could avoid or substantially lessen any of the significant effects of the project. The EIR will identify the potentially significant impacts of the proposed Project. The findings of the EIR impact analysis will guide the refinement of an appropriate range of alternatives to be evaluated in the EIR that would avoid or substantially lessen significant impacts, while still meeting the project objectives. Alternatives suggested during the public scoping period would also be considered. The EIR will include a discussion of impacts associated with the No Project Alterative.

SAN FRANCISCO PLANNING DEPARTMENT ENVIRONMENTAL REVIEW NOTICE

Notice is hereby given to the general public of the following actions under the Environmental Review Process. Review of the documents concerning these projects can be arranged by calling (415) 558-6378 and asking for the staff person indicated.

NOTICE OF PREPARATION OF EIR AND NOTICE OF SCOPING MEETING

The initial evaluation conducted by the Planning Department determined that the following project(s) may have significant effects on the environment and that an Environmental Impact Report (EIR) must be prepared.

Case No. 2005.0164E: Regional Groundwater Storage and Recovery Project

The San Francisco Public Utilities Commission (SFPUC) is proposing the Regional Groundwater Storage and Recovery Project to provide surface water to the cities of Daly City and San Bruno and the California Water Service Company (Cal Water) (collectively referred to as Partner Agencies), to be used by these agencies in lieu of pumping groundwater during normal and wet years. The Partner Agencies currently use groundwater as one of the sources of their drinking water supply. The supply would be partially replaced by surface water supplies from the SFPUC regional water system. The reduction of pumping by Partner Agencies would increase groundwater storage in northern San Mateo County within the southern portion of the Westside Groundwater Basin, known as the :South Westside Groundwater Basin." The Westside Groundwater Basin spans northern San Mateo County and the City and County of San Francisco. Stored groundwater would be pumped during periods of insufficient surface water supplies (i.e., dry years). As part of the proposed Project, SFPUC would construct new groundwater production well facilities in the cities of Colma, Daly City, South San Francisco, San Bruno, Millbrae, and unincorporated San Mateo County that would be operated by SFPUC and the Partner Agencies. Well facilities would be connected to Daly City, San Bruno, Cal Water, or SFPUC distribution systems.
The project is part of the SFPUC's Water System Improvement Program (WSIP). The WSIP was adopted in October 2008 to improve the SFPUC's regional water system with respect to water quality, seismic response, water delivery, and water supply to meet water delivery needs in the service area.

Notice is hereby given to the general public as follows:

1)A Notice of Preparation of an EIR was published on June 24, 2009 by the Planning Department in connection with this project.

2)Public comments concerning the scope of the EIR will be accepted from June 24, 2009 to July 28, 2009, 5:00 p.m. Mail written comments to the San Francisco Planning Department, Attn. Bill Wycko, Environmental Review Officer, Regional Groundwater

Storage and Recovery Project NOP, 1650 Mission Street, Suite 400, San Francisco, CA 94103. Comments also may be submitted by fax to (415) 558-6409, or sent by email to diana.sokolove@sfgov.org.

3)The San Francisco Planning Department will hold a scoping meeting starting at 7:00 p.m. at the South San Francisco Municipal Services Building, Community Room, 33 Arroyo Drive, South San Francisco, CA. Preceding the Scoping Meeting, the San Francisco Public Utilities Commission will hold a Public Information Session from 6:15-7:00 p.m.

SAN FRANCISCO PLANNING DEPARTMENT NVIRONMENTAL REVIEW NOTICE

Notice is hereby given to the general public of the following actions under the Environmental Review Process. Review of the documents concerning these projects can be arranged by calling (415) 575-9025 and asking for the staff person indicated.

PRELIMINARY MITIGATED NEGATIVE DECLARATION

The initial evaluation conducted by the Planning Department determined that the following projects could not have a significant effect on the environment, and that no environmental impact report is required. Accordingly, a Preliminary Mitigated Negative Declaration has been prepared.

Public recommendations for amendment of the text of the finding, or any appeal of this determination to the Planning Commission (with $500 filing fee) must be filed with the Department within 20 days following the date of this notice. In the absence of an appeal, the Negative Declaration shall be made final, subject to any necessary modifications, 20 days from the date of this notice.

2008.1286E: 1100 Ellis Street/Sacred Heart Cathedral Preparatory Theatre. The 61,105 square?foot project site (Assessor's Block 0711, Lot 031) is located on the north side of Ellis Street, on a block bounded by Gough, Ellis and Laguna Streets, and Geary Boulevard, within the Western Addition neighborhood. The site is located in an RM-4 (Residential Mixed-Use, High Density) District and 80-B Height and Bulk District. The proposed project involves the construction of a new theater, renovation of two existing buildings, and construction of a new elevator within the Sacred Heart Cathedral Preparatory school campus. The proposed theater would be located within the existing interior courtyard of the campus, would total approximately 11,513 square feet, would be 36 feet 9 inches in height, and would seat approximately 299 people. The proposed project would not result in an increase in the number of students or staff. (FORDHAM)

NOTICE OF PREPARATION OF EIR AND NOTICE OF SCOPING MEETING

The initial evaluation conducted by the Planning Department determined that the following project(s) may have significant effects on the environment and that an Environmental Impact Report (EIR) must be prepared.

2005.0164E: Regional Groundwater Storage and Recovery Project - The San Francisco Public Utilities Commission (SFPUC) is proposing the Regional Groundwater Storage and Recovery Project to provide surface water to the cities of Daly City and San Bruno and the California Water Service Company (Cal Water) (collectively referred to as Partner Agencies), to be used by these agencies in lieu of pumping groundwater during normal and wet years. The Partner Agencies currently use groundwater as one of the sources of their drinking water supply. The supply would be partially replaced by surface water supplies from the SFPUC regional water system. The reduction of pumping by Partner Agencies would increase groundwater storage in northern San Mateo County within the southern portion of the Westside Groundwater Basin, known as the "South Westside Groundwater Basin." The Westside Groundwater Basin spans northern San Mateo County and the City and County of San Francisco. Stored groundwater would be pumped during periods of insufficient surface water supplies (i.e., dry years). As part of the proposed Project, SFPUC would construct new groundwater production well facilities in the cities of Colma, Daly City, South San Francisco, San Bruno, Millbrae, and unincorporated San Mateo County that would be operated by SFPUC and the Partner Agencies. Well facilities would be connected to Daly City, San Bruno, Cal Water, or SFPUC distribution systems. The project is part of the SFPUC's Water System Improvement Program (WSIP). The WSIP was adopted in October 2008 to improve the SFPUC's regional water system with respect to water quality, seismic response, water delivery, and water supply to meet water delivery needs in the service area.

P R O C E E D I N G S

JULY 9, 2009 7:02 P.M.

INTRODUCTION

MS. SOKOLOVE: Hi. Good evening. Thank you for coming tonight.

Welcome to tonight's Public Scoping Meeting for the Regional Groundwater Storage and Recovery Project.

Can everyone hear me?

My name is Diana Sokolove, and I'm a Senior Environmental Planner with the San Francisco Planning Department, and I'll be the moderator for tonight's meeting.

So, I just wanted to review with you briefly the purpose of the meeting tonight for those of you who may be unfamiliar with the environmental review process.

Essentially, I'm here to hear from you. And I want to hear your comments on the scope and focus of the proposed project that's sponsored by the San Francisco Public Utilities Commission.

Your comments tonight can help me understand the depth of analysis that I need to perform in the

Environmental Impact Report, the alternatives to the proposed project, et cetera. So, we really want to understand what you think about the environmental effects of the project. So, that's the main reason why

I'm here tonight.

Here's our agenda: I'm going to introduce some folks from the project team here from the City and County of San Francisco and some other folks who are here from the partner agencies.

I'll make a brief presentation about the environmental review process in general, and then a representative from the San Francisco Public Utilities Commission will give a brief presentation and overview of the proposed project. Then we'll take your comments, and I'll make some closing remarks, and you can all go home.

So, just some reminders: If you haven't already, please sign in at the front desk. That's our way of keeping in touch with you, unless, of course, you don't want us to keep in touch with you, but that is our way to keep track and make sure that you receive our notices and publications regarding this project, so please do sign in. Pick up copies of the meeting materials, such as the Notice of Preparation.

And if you would like to speak tonight, you'll

fill out one of these yellow cards, please, and you can hand those cards to Pat and she'll give them to me.

And if you don't want to speak tonight, but you want to submit comments, you can fill out one of these sheets of paper. (Indicating) They're at the front desk, and I think we have some up here as well so you can submit some written comments.

And if you so choose, when we're done with the presentation, you can speak directly to the Court Reporter here and she can transcribe your comments directly.

Please do hold all of your comments until the end of the meeting so that we can -- I'm sorry -- until the end of the presentation so that we can get through the presentation as quickly as possible.

And I know you all have cell phones and pagers and lots of beeping things, so just turn those off. And if you do need to take a call, feel free to step outside. And I know there are restrooms. If you go out this door, make a right. And there is also a water fountain over there.

---oOo---

ENVIRONMENTAL REVIEW PROCESS OVERVIEW

MS. SOKOLOVE: So, again, my name is Diana Sokolove. I'm with the San Francisco Planning Department, and the Planning Department is the lead agency for performing the environmental review of this proposed project under the California Environmental

Quality Act, or CEQA, and the project sponsor is the San Francisco Public Utilities Commission.

And here tonight is the Project Manager, Greg Bartow. And we also have Sue Chau, who is the Environmental Project Manager. Michele Liapes in the back with communications, and also, Les Chau with Kennedy/Jenks, who's a designer working with the Public Utilities Commission.

And I think there's some folks from the partner agencies here.

MR. BARTOW: I just want to acknowledge our three partner agency representatives that are here tonight: Patrick Sweetland from Daly City, Tom Salzano from Cal Water, and Steve Davis from the City of San Bruno.

Also, two managers from the San Francisco Public Utilities Commission that are here tonight: Andrew Degraco, Manager of our Water Quality Department,

and Paula Kehoe, Director of Water Resources.

MS. SOKOLOVE: So, I did want to talk to you a little bit about the California Environmental Quality Act. Proposed projects do require environmental review under CEQA before they can be considered for approval. So, again, we're here tonight to hear your comments on what the environmental effects of the project will be so that we can be sure to disclose all of those facts in the environmental document.

And again, as I explained, for projects that are sponsored by or within the City and County of San Francisco, including San Francisco Public Utilities Commission Projects, CEQA is implemented by the San Francisco Planning Department, and that's who I represent.

Here are the objectives of CEQA -- I'll just read these off to you: To prevent environmental impact of proposed projects; identify ways to avoid or reduce environmental impacts; support the agency decision-making process, such as planning commissions or the San Francisco Public Utilities Commissions or any of the partner agencies commissions, and also, resource agencies; to encourage public participation -- so, this is another reason why we're here tonight -- and to enhance interagency coordination.

So, what will our Environmental Impact Report do. Well, the -- the meat of the Environmental Impact Report is an analysis of the environmental effects of the project and looking at alternatives to the proposed project that could reduce or avoid or lessen environmental effects.

So, it's going to have a really good description of the proposed project, and it's going to talk about the environmental effects of the project. And those environmental effects range from air quality impacts, transportation impacts, traffic, hazardous materials impacts, impacts on plants and wildlife. Those kinds of things.

And then there will be a section on ways that we can reduce the environmental impacts of the project, be that through mitigation measures or through alternatives to the project.

So, now, a representative from the San Francisco Public Utilities Commission, Greg Bartow, will talk to you a little bit about the project itself.

---oOo---

PROJECT OVERVIEW

MR. BARTOW: Thanks, Diana.

Good evening, everybody. I'm Greg Bartow, the Project Manager for this project, and I want to thank everybody for coming out this evening to learn more about the project. I'm just going to give you a brief overview of the project. The Notice of Preparation goes into the project in a lot more detail. There's also information on our Web site, and materials on the back of the table.

First, I want to just talk about the

San Francisco Public Utilities Commission in general. We're a wholesale water provider and resale water supplier in the San Francisco Bay Area.

We supply 2.4 million residents in the Bay Area. About a third of those are San Francisco retail customers, and two-thirds of those are wholesale suburban customers, as -- the light area around the Bay shows the service area, which is a portion of the East Bay, a portion of the South Bay, almost all of San Mateo County, and all of San Francisco. (Indicating)

The Water System Improvement Program was a voter-approved bond measure in 2002 to do seismic restoration or rehabilitation of the project -- of a

number of our projects, including pipelines, reservoirs, and treatment plants.

It also included a component to diversify our water supply, and that's where this project fits in. It includes this project, as well as drilling new wells in San Francisco for a water supply, recycled water facilities, as two other examples.

So, on the need for the project, so that it -- this is basically a dry-year water supply project, and what it is designed to do is to meet our commission-approved 80 percent reliability goal, which said another way is, we have -- the Commission has adopted a policy to not -- in any dry year, not have our cutbacks to be more than 20 percent so we wouldn't have mandatory rationing greater than 20 percent.

But this is part of the project that would need to happen to keep that mandatory rationing at no greater than 20 percent in any one year or any series of years.

Okay. So, now I'll take you into the Westside Basin here. And so, the Westside Basin is about 40 square miles. It extends from Golden Gate Park to the north, all the way down to Burlingame.

And the focus of this project is the South Westside Basin. And we're working with three partner

agencies: Daly City to the north, Cal Water, which serves South San Francisco and Colma and some unincorporated areas in San Mateo County, and then the City of San Bruno.

This is a Conjunctive Use Project, and so to -- that term means the use of the -- the managed use of groundwater and surface water. And what really works out for this part of the basin is that these utilities already use groundwater to meet a portion of their water supply needs, and they have an ability to use San Francisco surface water supplies.

So, what is groundwater. Groundwater is water that has -- that is in the subsurface that has been recharged, either from rainfall or from streams and irrigation.

And so, what this map or this cross section shows is the unsaturated zone above the groundwater table and a typical well. (Indicating) So, just schematically just to give you a little overview of what we're talking about. Groundwater.

How would the project work? So, there's sort of the three components of the project here. The existing conditions, which is the cross section on the upper -- just first of all, I think a simple way to look at the west -- South Westside Basin, if you think about

it as a bathtub full of sand, and then the water levels, due to historic pumping, have been depressed, and so, there's some available storage.

So, that bathtub is roughly a half or two-thirds full of water, and the space between the sand grains above that water has available storage space to it. And so, currently, water levels are, in some cases, 200 feet below sea level. There's a significant amount of available storage in this underground reservoir. And that's what we want to utilize for this project.

So, the existing condition is that there's -- the pumping has decreased and stabilized over the years, and the existing conditions is that there are those municipal pumpers and some other irrigation pumpers in the basin that are used in the basin.

And the way the project works is, in normal and wet years, when we have water, extra water within the system, we have no -- we don't have places to put it. We top off our reservoirs, and there's no other location where we can store this. And the South Westside Basin provides such a storage location.

So, you can see what we do is, in normal and wet years, we would supply to those three partner agencies more surface water and they would reduce their pumping from the groundwater basin. By reducing the

groundwater pumping, that allows the natural recharge to build up.

So, we're not talking about injecting water. We're not talking about recharged ponds like some other utilities. It's just going to be the natural recharge that accumulates in the basin over time. So, that's the middle slide. That's how we've increased the storage there.

And then when we get to a drought, we will have installed 16 new wells in the basin that we can draw from this stored water, and then those partner agencies -- the City of Daly City, Cal Water, and San Bruno -- would turn their existing wells back on and pump the amount of water they had previously pumped, and will be able to pump from these new wells.

So, that's the benefit of the project, is being able to recover that stored water.

To say this a little differently, we'll just look at those same time slices that we were showing from top to bottom, only this time it's left to right.

So, under existing conditions right now, if you take those three agencies together -- Daly City, Cal Water, and San Bruno -- and look at how much water they're using collectively, they're using 14.5 million gallons per day of surface water and 5.7 million gallons

per day of groundwater. So, this is collectively. In Daly City and San Bruno, it's more 50/50. In Cal Water, it's a smaller percent, but it averages out to be about a third, two-thirds.

So, then we get into the storage component of the project, and in wet or normal years, they'll reduce their pumping. So, you can see the blue portion of the chart is decreasing.

And then we're adding -- we're providing more surface water to them. So, that's how the water then -- by reducing that pumping, then that's allowing groundwater to accumulate in the basin.

Then the payout where this project makes -- provides the benefit is during the dry year. And during the dry year, we would reduce our surface water deliveries to those utilities, and then we would pump through those 16 new wells -- the middle, the darker blue portion of the water (Indicating) -- and then they would return to pumping their previously pumped amount of water.

This is -- this provides a regional benefit to all the 2.4 million customers. It sort of helps float everybody's boat by having this additional pumping -- pumped groundwater in dry years in this project.

I'll talk now more about how we got these well

sites. How did we get to these 16 well sites. Initially, we started with 48 sites that we looked at throughout the basin. We were looking for sites on properties we owned, on other public properties, and private properties.

We ranked those relative to a number of criteria, but, for example, distance to transmission lines, location of where they are in the basin. The center of the basin is deeper, so we wanted to stay away from the sides of the basin, which are shallower. We wanted to stay away from potential contaminating activities like underground storage tanks.

And so, we winnowed that down from 48 to 19 sites that are in the Environmental Impact Report that are listed in this Notice of Preparation. And then of those, we want to build up to 16 sites. So, there's maps in the Notice of Preparation, and this exact map is in there.

But just to take you through -- so, starting in the north -- and these are a series of three overlapping maps showing you the location of these 19 sites. So, that's in the Daly City and Colma area, Colma, South San Francisco area, and then San Bruno and down to Millbrae.

So, let me go over the overall project

description. So, we're working on an agreement with these three utilities to store up to 61,000-acre-feet of water in the South Westside Basin. That's about as much water as in our Crystal Springs Reservoir. If you ever go down 280 or cross over 92 to go to Half Moon Bay, you're going through upper and lower Crystal Springs Reservoirs.

Starting this spring, there were 54,000-acre-feet, and at that time the reservoir was full, so, this is a lot of water that we're able to store in this -- this South Westside Basin. The scope is to develop 7.2 million gallons per day pumping capacity, and to be able to pump that for 7 1/2 years.

So, the map is, if you pumped that amount at that rate for that amount of time, that would equal 61,000-acre-feet. And we'd only pump the stored water, the water that we had stored through the exchange program with those agencies.

I mentioned this before, the project is to construct 16 wells. Each of the facilities would also have pipelines there. There would be electrical connections. There would be connections to the stormwater in the sanitary sewer.

We'd disinfect the water per the California Department of Public Health requirements. We'd provide

other treatment, if needed. If the water naturally doesn't meet the drinking water standards, then we would treat it to be below those standards. And then the wells would be connected to either Daly City, San Bruno, Cal Water, or the SFPUC pipelines. It will be a combination of those up and down the basin.

I want to emphasize that the water will -- you'll continue to have high-quality drinking water from this project. The groundwater will be in compliance with the California Department of Public Health requirements. There will be disinfection of the water where we'll have a monitoring program, and in most cases, the groundwater will continue to be blended with San Francisco's imported surface water.

Just a typical site layout. So, this is a site in South San Francisco off of Hickey Boulevard. We own the right of way along this proposed site, and the -- this is the well. This is the building. (Indicating) These other lines are existing pipelines or proposed pipelines. (Indicating)

As I mentioned, we're going to need connections to the sanitary sewer, storm drains, etc. And then there's a larger line drawn around this that would be the areas of construction, so when we're constructing the facility, we'd have a larger area that

would be impacted, and then we'll end up with a smaller building there when we're all done.

This is a sample facility from Southern California, a well station. This is a well only. If we have to have disinfection or treatment, the facility could be twice that size.

And then I'll turn it back over to Diana.

MS. SOKOLOVE: So, here's our environmental review schedule. We distributed the Notice of Preparation on June 24th of this year. Tonight is our Public Scoping Meeting. The scoping period ends on July 28th, so that's the last day that we'll be accepting scoping comments. And then we begin our draft Environmental Impact Report. We hope to publish the draft Environmental Impact Report next summer, and then we would release that Environmental Impact Report for a 45-day review. Once we get comments back, we will prepare responses to comments, and we would release the response-to-comments document, or the final Environmental Impact Report the following year. We hope to certify in mid 2001.

So, here is your chance to give me your comments, and I'm just wondering if anyone has a speaker card, if they wanted to speak tonight.

Given the fact that we have a court

transcriber here, if you could stay up in the front of the room and sort of speak to her and the audience, that would be great.

---oOo---

PUBLIC COMMENT

PUBLIC SPEAKER: Hi. My name is Andrea Ouse. ← ORAL COMMENT 101
I'm the City Planner for the Town of Colma. Thank you very much for the Scoping Meeting tonight. I'm here on behalf of the Town of Colma, its residents, and property owners.

First of all, I think in concept, the Town agrees with and respects the type of work that's being done here. It's an overall public good. I do think that there are some considerations that maybe haven't been vetted out quite yet.

Um, one of the things that concerns us in the Town is the test wells. The test wells appear to be being handled as a separate project and not encompassed as part of a cumulative review of the recharge project.

So, I understand from talking to staff, and from a workshop that was held in Colma, that it's -- they're being considered under a categorical exemption.

Also, what I understand is there's a cluster of wells. There's approximately five or six different sites in our town of Colma, and there's many others throughout the stretch.

There are approximately five different wells in each site, so there's a number of very large, deep holes that will be dug throughout our community, and we're really not sure that that warrants a categorical exemption under CEQA, and we would appreciate being forwarded any paperwork that's been already developed on the test-well issue so that we have the opportunity to review and comment on it.

The scope of those test wells, we really didn't know to much about it, but we would also appreciate it, if there's any project description on those test wells, to be sent that information.

On the project description of the storage project here, we don't feel at this point that it is quite adequate to describe the -- sort of the depth, and again whether or not this will include clustering. I didn't know that there's going to be buildings associated with each well site.

Maybe there is or isn't, but this is kind of -- this was new information for me. We do have some pretty significant concerns if buildings are going to be associated with each well site and where those are going to be located and what they're going to look like.

For any of you not familiar, Colma has 76 percent of its land in cemetery use. And there's -- you know, we try to keep our policies in line with a very tranquil and serene environment. Our cemeteries have been there over a hundred years and they use a lot of the groundwater to irrigate their property, so we have a very distinct, vested interest in maintaining some sort of rights associated with that usage.

At this point I'm not quite sure what the management structure is going to be in terms of the assertion of authority over this -- this aquifer, so I think the project description should include a description of what that breakdown is going to be and what that authority -- who's going to have the authority over this water, and if it's going to change the rights and the ownership of that water to the partner agencies or different entities, other than those that are already existing and have those rights to the water.

One of the things I would like to see in the Environmental Impact Report is some sort of study of the potential settlement issues associated with recharging the aquifer and deleting the part of the aquifer.

Since it appears to be either a gradual decrease in the amount of water in the aquifer right now, is there going to be any consideration for potential settlement issues with sort of a more active management of the aquifer?

And that concludes my comments. Thank you.

MS. SOKOLOVE: Thank you.

Did anybody else want to make any comments tonight?

PUBLIC SPEAKER: Good evening. My name is Peter Drekmeier. I'm with the Tuolumne River Trust. ORAL COMMENT 102

And I'm curious if the EIR is going to look at the impacts of -- it sounds like it might divert an extra 6.7 million gallons of water per day from the Tuolumne in wet years, and I'm wondering if in addition to what was studied in the program EIR for the WSIP, that that would be looked at.

If that wasn't the plan, I would encourage you to do that, because there's going to be additional information coming out at the end of this year or early next year. The PC is doing a biological study of the stretch below Hetch Hetchy as part of the settlement on the Kirkwood Powerhouse Agreement in 1988. So, we're going to have additional information that wasn't available at the time of the WSIP, and that would be good to incorporate that.

I'd also encourage you to look at the recharge

of the groundwater with stormwater so that we might be able to tap it sustainably ongoing even in wet years and rely less on the Tuolumne River.

Thank you.

MS. SOKOLOVE: (Indicating)

PUBLIC SPEAKER: Good evening. I'm Kathryn Slater-Carter, and I am a business owner in Daly City and a property owner in Pacifica. ORAL COMMENT 103

I have a question, actually, about whether the rate of recharge for the basin has been calculated and is part of this, given that during the dry years there would be more water taken out of it, how long will that water supply be good for.

There's substantial impervious surface in the basin, and to Peter's earlier comments, I think it might be worthwhile to be looking at treated stormwater runoff, since most of the cities do have stormwater drainage systems in them.

The other question is, What will the cost of the -- from the increased use of Hetch Hetchy water be? It's a very expensive water. I'm sure that Daly City is able to blend its rates to keep the cost down by using groundwater.

Is this going to cause me, as a business owner that uses a significant amount of water, to see an

increase in my rates?

Thank you.

MS. SOKOLOVE: (Indicating)

PUBLIC SPEAKER: My name is Jim Stark. I reside in San Francisco, and I live in the area known as "Lakeshore" or "Lakeshore Acres," and for many years, our organization, the Lakeshore Acres Improvement Club, has been concerned with lake levels at Lake Merced, and we hope that the Environmental Impact Report will examine it and respond to all the concerns that are already known regarding lake levels at Lake Merced. ← ORAL COMMENT 104

Thank you.

MS. SOKOLOVE: (Indicating)

PUBLIC SPEAKER: I'm going to talk to you since you're the one who's writing everything the EIR, and I'm happy to have everybody who's here hear me say what I have to say.

My name is Bob Maddow. I'm an attorney. I represent a number of golf courses throughout the basin. Several of them have switched from use of groundwater from this very same aquifer to use of recycled water. That's been an important achievement that the City and County of San Francisco and the City of Daly City are very proud of, and rightly so, and so are those golf courses. And they're very satisfied with the recycled ← ORAL COMMENT 105

water as a substitute supply for the groundwater that was being pumped.

I have to say that a number of my clients, which are owners of private wells in this same basin who have the legal right to use groundwater within this basin -- that they find it somewhat ironic that we're now looking at more than doubling the production of groundwater from this aquifer, which they have worked hard and they are paying good money to preserve, and they're very concerned about making sure that in the long run, the doubling of the production of this aquifer is thought through very carefully before it's undertaken.

Greg talked about the aquifer and analogized with the bathtub full of sand, and that's pretty good, because he did not do something that I have seen suggested, or at least implied, in some of the things that I have read about the Conjunctive Use Program, and that's an intent to analogize this to a lake. It's not a lake.

You've got -- Greg talked about the fact that the groundwater levels within this basin are depressed dramatically from years of pumping, but it's still an aquifer that has enormous productivity and enormous potential for storage, but nobody knows what's going to

happen when you refill it.

There's been a pilot program in which something on the order of 15,000-acre-feet was, in fact, recharged into this aquifer as a result of the same kind of in-lieu program that you're talking about on a larger scale now, but beyond that 15,000-acre-foot pilot program, nobody really knows exactly what's going to happen.

So, I think it's very important that the Environmental Impact Report describe how it is that that -- the effects of refilling that aquifer will, in fact, be measured, both from the standpoint of its long-term productivity, from the standpoint of the impact of private well owners who still have the legal right to use water from that aquifer.

And with regard to water-quality issues, I realize that the water that is extracted from that basin now for municipal purposes is a high-quality water. In fact, the water quality in this area is excellent, if you compare it with what you can find in most of California and much of the nation.

But you're dealing with refilling a basin that has been empty, and a significant portion of that basin underlies something that is proudly called "The Industrial City." I don't know what kind of quality

considerations might crop up once that basin is refilled. In other words, are there contaminants that will be remobilized? Let me put it that way.

Greg mentioned leaking underground storage tanks. I think it could conceivably go beyond that. I don't have any particular contaminant in mind or source of contaminants in mind.

It just occurs to me that there's the potential for remobilization of contaminants that might have been deposited there through industrial activity long, long ago and during the time when this aquifer was, in fact, being hit pretty hard.

From the standpoint of private well owners throughout the basin, both those whom I represent and others whom I know to exist, there needs to be a clear understanding of the possibility for mutual interference. I'm aware of a little work that's been done with regard to mutual interference. I'm not aware of all that has been done or will be done.

I hope that that issue is, in fact, discussed in the environmental analysis and in the technical memoranda that accompanies the environmental analysis so that the owners of private wells will understand exactly what they can anticipate. This is not an adjudicated basin.

I really appreciate the comments made by the woman from Colma. What are the legal implications of the type of program that you are actually talking about undertaking? And what are the rights of the private-property owners who are going to find that as a result -- who might find -- we'll know from your EIR, I hope -- that the rights that they have to extract water for productive, beneficial uses from this basin are adversely impacted?

They might -- might some of their wells be rendered obsolete? Might some of their wells have to be deepened? Might they need new pumping arrangements? Might they have to move to entirely new water supply arrangements as a result of this?

We don't know any of that yet. Those are among the suite of issues that need to be addressed. And, of course, there is the overlay of the legal issue that has been referred to a couple of times tonight.

All in all, it's an exciting project. It's the kind of project that should be done. It needs to be done in a careful, integrated way, looking at all the opportunities.

There was a reference to -- by Mr. Drekmeier to the possibility of using stormwater as a component of the recharge of this basin. And that obviously is a

potential. I'm not quite sure how you intend to look at that, but it is an issue that needs to be addressed.

A parallel issue is one that comes right out of your Water System Improvement Program, and that's the additional use of recycled water as a source of water for irrigation purposes throughout the portions of the basin where it is not now available.

I know that San Francisco is working hard with Daly City to extend the use of the tertiary water that's produced at the Daly City plant, to move it to Harding

Park, and I know at various times, San Francisco has considered other aspects of the water recycling program that would be a part of and would work in conjunction with the WSIP program.

How does that work throughout the balance of the Westside Basin?

There are a number of opportunities there, it would seem to me, for there to be a recycled water program that might allow you to get even more bang for your conjunctive use if you were to get those two things in parallel.

In other words, integrated water resources management. Paula Kehoe's favorite term. Integrated water resources management needs to be considered and analyzed in this EIR just as it would need to be

considered and analyzed in an EIR for a stormwater treatment program of the type Mr. Drekmeier referred to for an extended recycled water program.

We look forward to participating. We appreciate the opportunity, and hope to be able to submit comments by the 28th and participate in the balance of the project.

MS. SOKOLOVE: Does anybody else want to speak tonight?

PUBLIC SPEAKER: Good evening. My name is Paul Perkovic. I live in Montara, and I'm on the Board ← ORAL COMMENT 106
of Directors along with Kathryn of the Montara Water and

Sanitary District which serves the Montara, Moss Beach area.

Our water -- our district does not receive water from the Hetch Hetchy system. However, the neighboring district to our south, Coastside County Water District, does receive water from Hetch Hetchy. And because the entire coastside is affected by water supplies that meet our domestic and agricultural needs, I'm interested in how this project may stabilize the water supplies that would be available from Hetch Hetchy to meet the coastside needs.

Coming from the coastside, I have a different perspective on a couple of the items. I just got

through the materials this evening and scanned through them fairly quickly, but we have a frequent problem where we lose power, and I didn't see any plans for emergency generators, backup generators in any of the well pump-housing or treatment facilities.

Certainly, I think that it would be prudent, unless your power supplies are much more reliable here than they are on the coast, that you have some provision for emergency power, unless you have 99.9 percent availability from your public power supplier. We often lose power for hours at a time, sometimes several days at a time, and backup power is necessary on all our facilities.

Secondly, before our district acquired the water system from the previous owners, (Inaudible) Corporation of California, there was an instance where an underground fuel tank that was used to store gasoline leaked into our -- one of the aquifers that served our community, and the resulting MTBE contamination meant that two of the major production wells were taken out of service for a period of time, and that had a very dramatic impact on our district.

You mentioned that the siting looked at potential contaminant sources. However, there are numerous gas stations located throughout the urbanized

area in the basin area, and I don't know if any of those have had any leakage problems with MTPE-supplemented fuel.

And I share the concern of the attorney who just spoke, in that some of the materials -- some of the contaminants may have adhered to the soil particles when water levels were at a lower level, and as the water levels are raised, they may be remobilized.

Um, those are the major concerns or questions I have that are directly relevant to the EIR scoping process. However, I have a number of other questions that are sort of business-related questions, and if I may, I'd like to just put those forward.

Kathryn raised the question about how the cost of the water would effect the relevant agencies. It looks to me like the plan is during years when there is an adequate supply, Daly City and South San Francisco and Cal Water would take additional water from Hetch Hetchy and not pump the groundwater wells.

Would they be paying the current Hetch Hetchy wholesale prices for the water that they take, or would that be treated as an advance of so many million acre feet or so many thousand acre feet that could be drawn on in the future?

This is particularly important, because the

price of an acre foot of water this year is about 17 percent less than the price of an acre foot of water next year, and about 21 percent less than the price of an acre -- or, cumulative, you know, 38 percent less than the cost of an acre foot two years from now.

So, if the agency is paying 2009 prices to purchase water to allow recharge, and then that agency can draw on that water two years from now when they otherwise would be paying much higher rates to purchase water from the Hetch Hetchy system, basically the other users of the Hetch Hetchy water, the Bay Area Water Supply and Conservation Agency, are underwriting the cost of water to the South City and Daly City and CalAm [sic] users.

If it's treated as an advance of water that is then repaid later by dry underground water basin, and the payments to Hetch Hetchy to SFPUC remain at the sort of average use and escalating price to pay for the seismic improvement program, that would seem to me to be more fair.

The second question that's related to that -- and maybe this is within the scope of the EIR, at least within our scope, the Bay Area Water Supply and conservation agency -- there's a very complex water allocation scheme, as I understand it, for drought

periods.

And agencies get some percentage of their water purchase in a base year, plus some percentage of their water purchased in the previous water year, and that affects the water supply assurance during a drought period so that it's based on sort of historic use and recent use to determine how much is delivered. Coastside County Water District is in a very unfortunate situation that their historic water use is very low, and during the planning for this year's drought, it was looking like if Hetch Hetchy -- if the SFPUC cut back 20 percent, their water delivery would be cut back 36 percent.

Now, how will those formulas apply for the agencies we're looking at here that are participants if they are taking delivery of a much higher quantity of water from the SFPUC system during the recharge period?

Then when the drought period comes, is their allocation much higher as a consequence?

Now, again, this may be something that's part of the contract negotiations. That's true.

And those are the only comments I have at the moment. Thank you very much.

(To Mr. Maddow) And I very much appreciated your comments, sir.

MS. SOKOLOVE: Anyone else?

(No response from the audience)

---oOo---

CLOSING REMARKS

MS. SOKOLOVE: I just wanted to let you know where you can send your comments, if you have any further comments.

If you didn't speak tonight, or even if you did speak tonight, and you want to submit some additional comments, you should feel free to send them to me at my E-mail address. You can fax them to my office or you can send them in by mail to the Planning Department through July 28th.

And I believe that all of this information is also on your agenda. It's in the Notice of Preparation, et cetera, but if you need my business card, I can give one to you.

And for more information, you can contact me. There's my phone number, my E-mail. Please do read the Notice of Preparation. We have extra copies here tonight, so if you'd like to take one with you, I can give you one.

And if you have questions or comments about

the project itself, you can contact the San Francisco Public Utilities Commission. And again, all of this information is on your agenda.

So, that concludes our presentation for this evening. And I really do want to thank you for coming tonight. Your comments were excellent, and we will certainly take them all into consideration when we're preparing the Environmental Impact Report.

Again, thank you very, very much for your time.

(Whereupon the Public Scoping Meeting was concluded at 7:49 p.m.)

---oOo---

STATE OF CALIFORNIA) SS.

I, Katy Leonard, CSR No. 11599, in and for the State of California, do hereby certify:

That the foregoing is a true, correct, and complete transcript of the Public Scoping Meeting made this date.

I further certify:

That I am not interested in the events of this action.

WITNESS MY HAND this 15th day of July, 2009.

SCOPING MEETING

REGIONAL GROUNDWATER STORAGE AND RECOVERY PROJECT

Environmental Impact Report

JULY 9, 2009

Scoping Meeting Purpose

- Hear your comments on the proposed scope and focus of environmental review of the proposed Regional Groundwater Storage and Recovery Project
- Help identify the following to be analyzed in depth:
  - ***Range of alternatives***
  - ***Environmental effects***
  - ***Methods of assessment***
  - ***Mitigation measures***

Scoping Meeting Agenda

- Introductions
- Presentation
  - ***Overview of Environmental Review Process***
  - ***Overview of Regional Groundwater Storage and Recovery Project***
- Public Comments
- Closing Remarks

Scoping Meeting Reminders

- Sign in at the table near the entrance.
- Pick up copies of meeting materials.
- If you would like to speak during tonight's hearing, fill out a speaker card.
- To make written comments, pick up comment cards.
  - ***Drop off at the end of the meeting***
  - ***Mail or fax later***
- Please hold all comments until the end of the presentation.

Project Team Introductions

San Francisco Planning Department
(Lead Agency under CEQA)

- ***Diana Sokolove, Senior Environmental Planner***

San Francisco Public Utilities Commission
(Project Sponsor)

- ***Greg Bartow, Project Manager***
- ***Suet Chau, Environmental Project Manager***
- ***Michele Liapes, Communications***
- ***Les Chau, Kennedy/Jenks Consultants***

ENVIRONMENTAL REVIEW PROCESS

California Environmental Quality Act

Proposed projects require environmental review under the California Environmental Quality Act (CEQA) before they can be considered for approval

For SFPUC projects, CEQA is implemented by the San Francisco Planning Department

CEQA Objectives

- Present environmental impacts of proposed projects
- Identify ways to avoid or reduce environmental impacts
- Support the agency decision-making process
- Encourage public participation
- Enhance interagency coordination

What will the EIR do?

- Provide a detailed description of the project and the existing environment
- Identify potential environmental impacts
- Identify ways to avoid or reduce significant environmental effects through mitigation or alternatives to the proposed project

PROPOSED REGIONAL GROUNDWATER STORAGE AND RECOVERY PROJECT

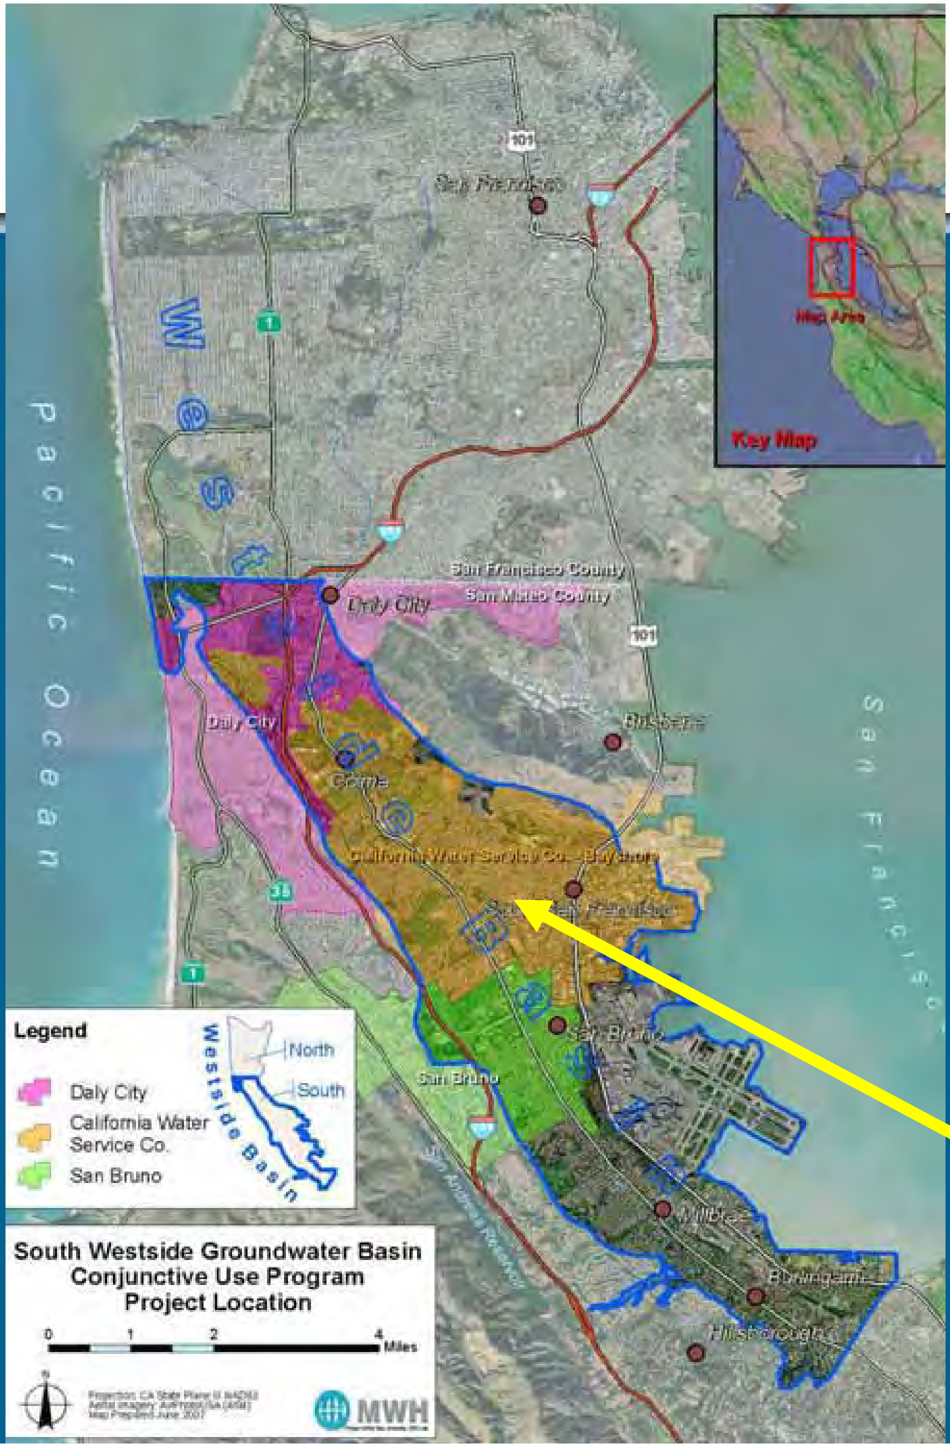
SFPUC Hetch Hetchy Water System

Water System Improvement Program (WSIP)

- Voter Approved November 2002
- More than 85 projects to:
  - ***repair, replace and seismically upgrade key water system facilities***
  - ***add new, redundant facilities to insure system reliability***
  - ***diversify water supply and increase dry year supplies***

Need for the Project

- Develop dry-year water supply
- Meet the 80% water supply reliability goal adopted by the SFPUC Commission



Partner Agencies:

City of Daly City

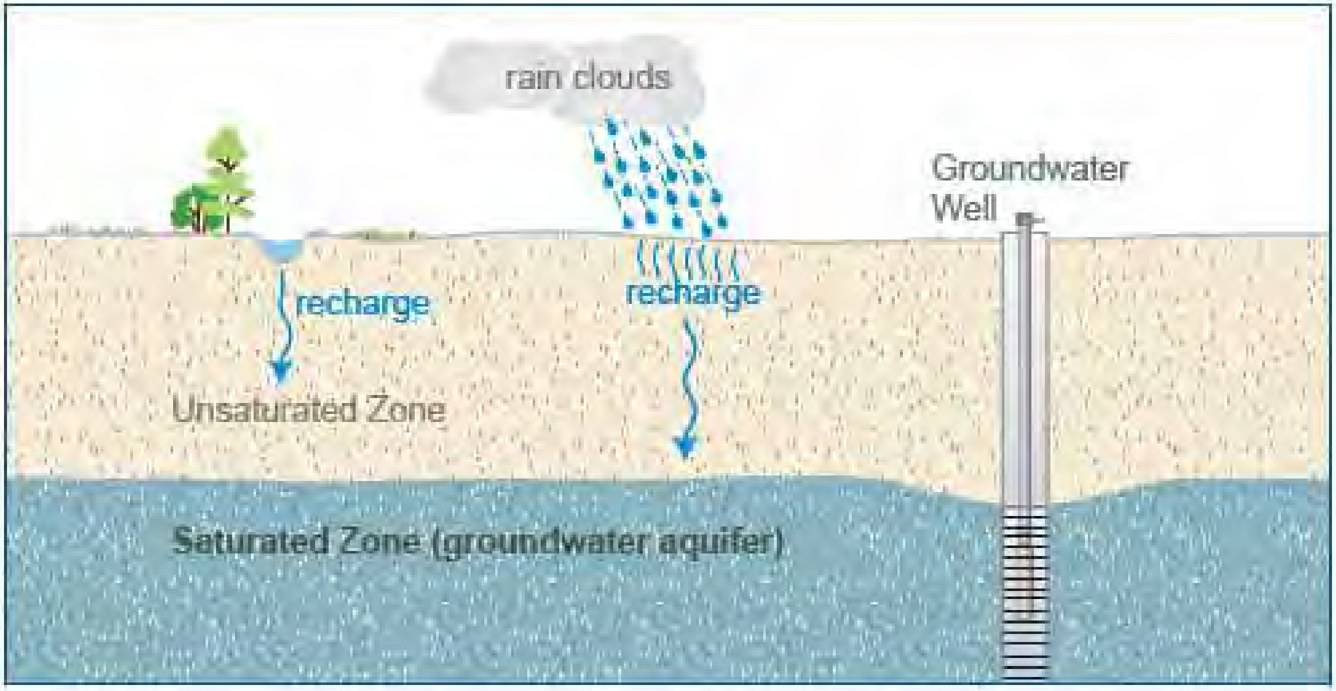
California Water Service Co

City of San Bruno

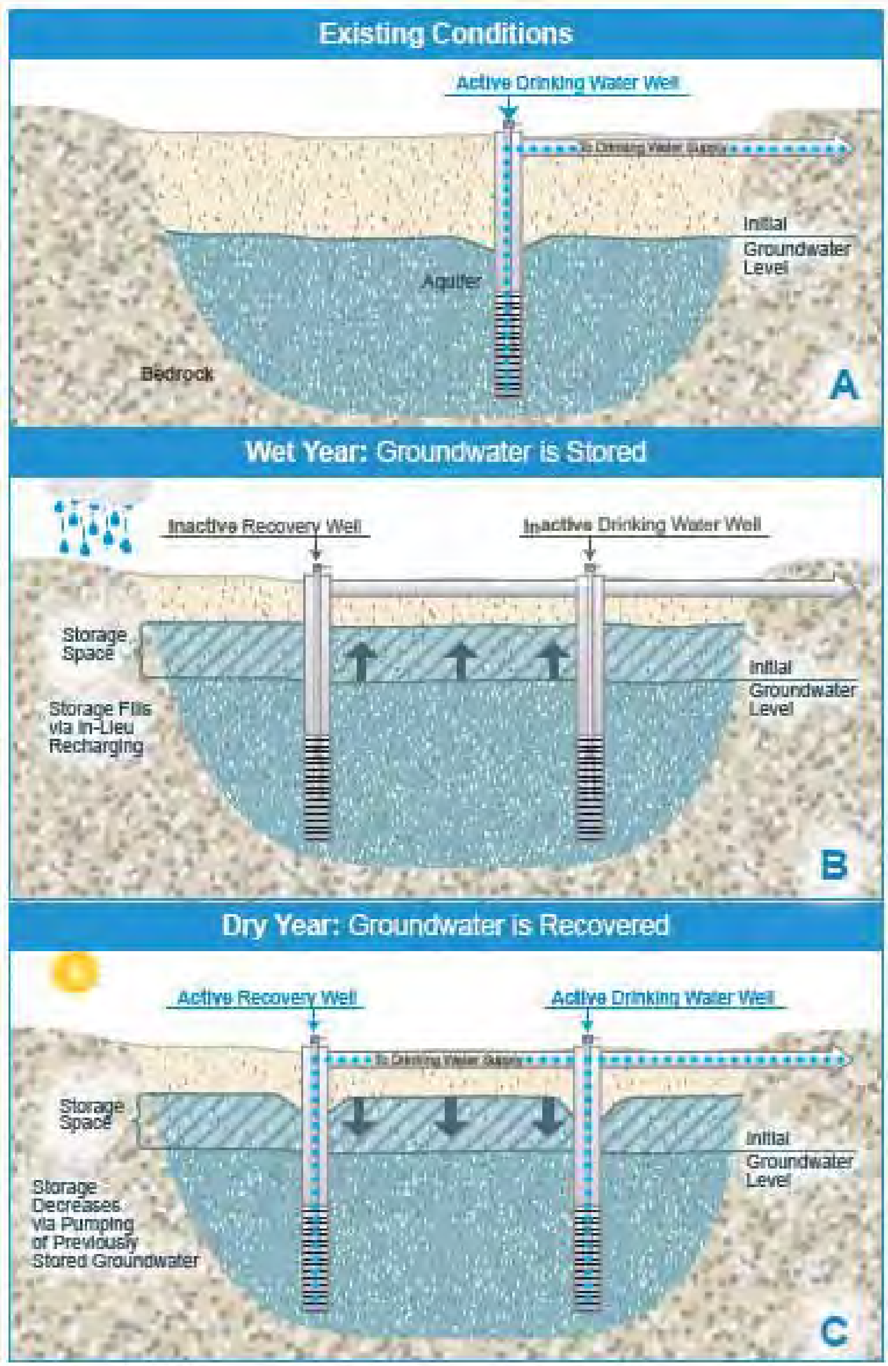
South Westside Groundwater Basin

What Is Groundwater?

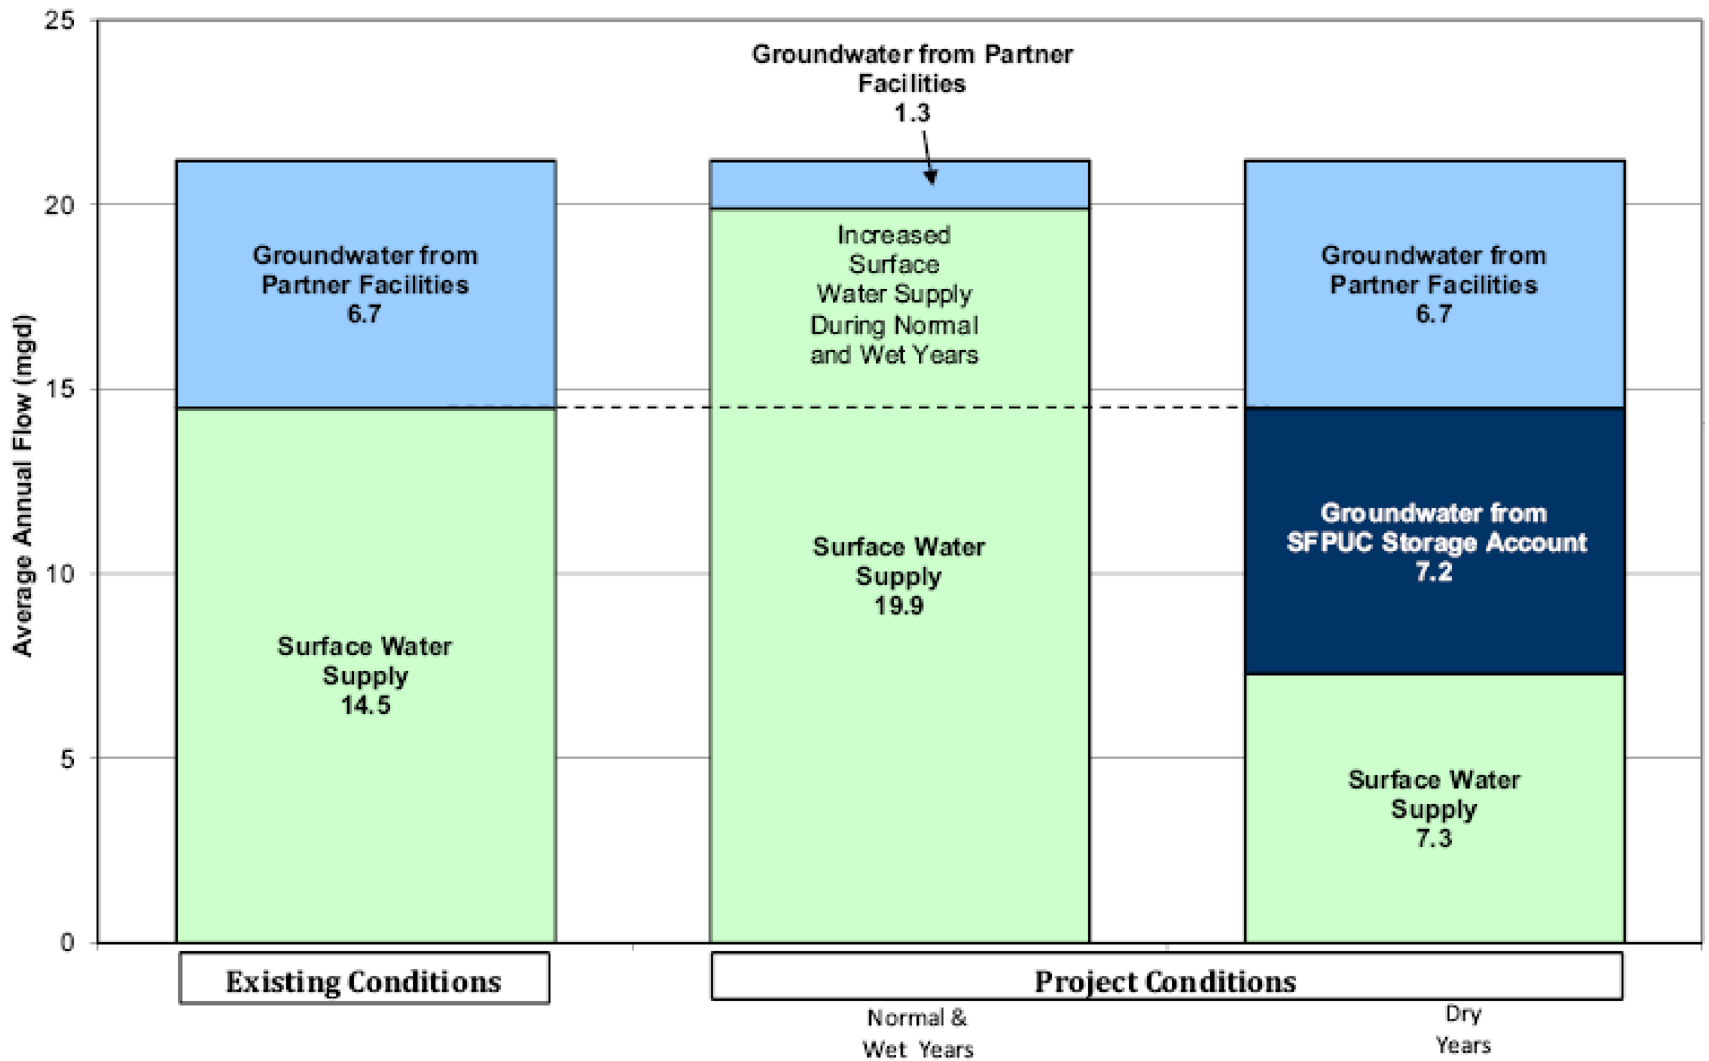
As rainwater or surface water seeps into the ground, it moves downward between soil particles and collects in an underground geologic reservoir. When such a reservoir can readily yield water to springs or wells, it is called an aquifer and is a potential source of drinking water.



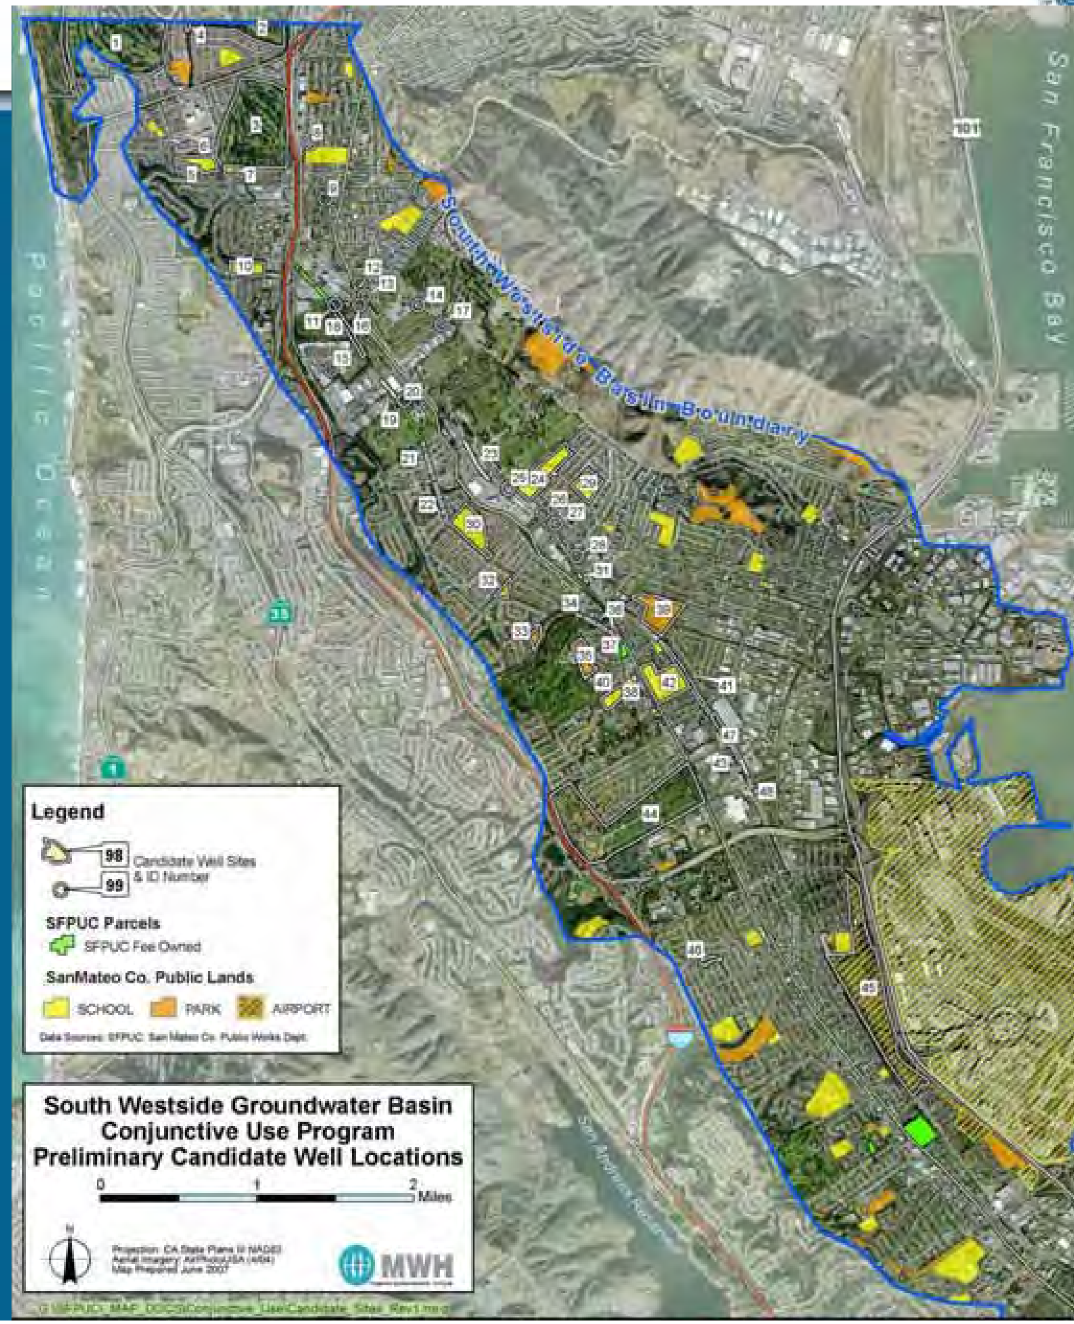
How Would The Project Work?



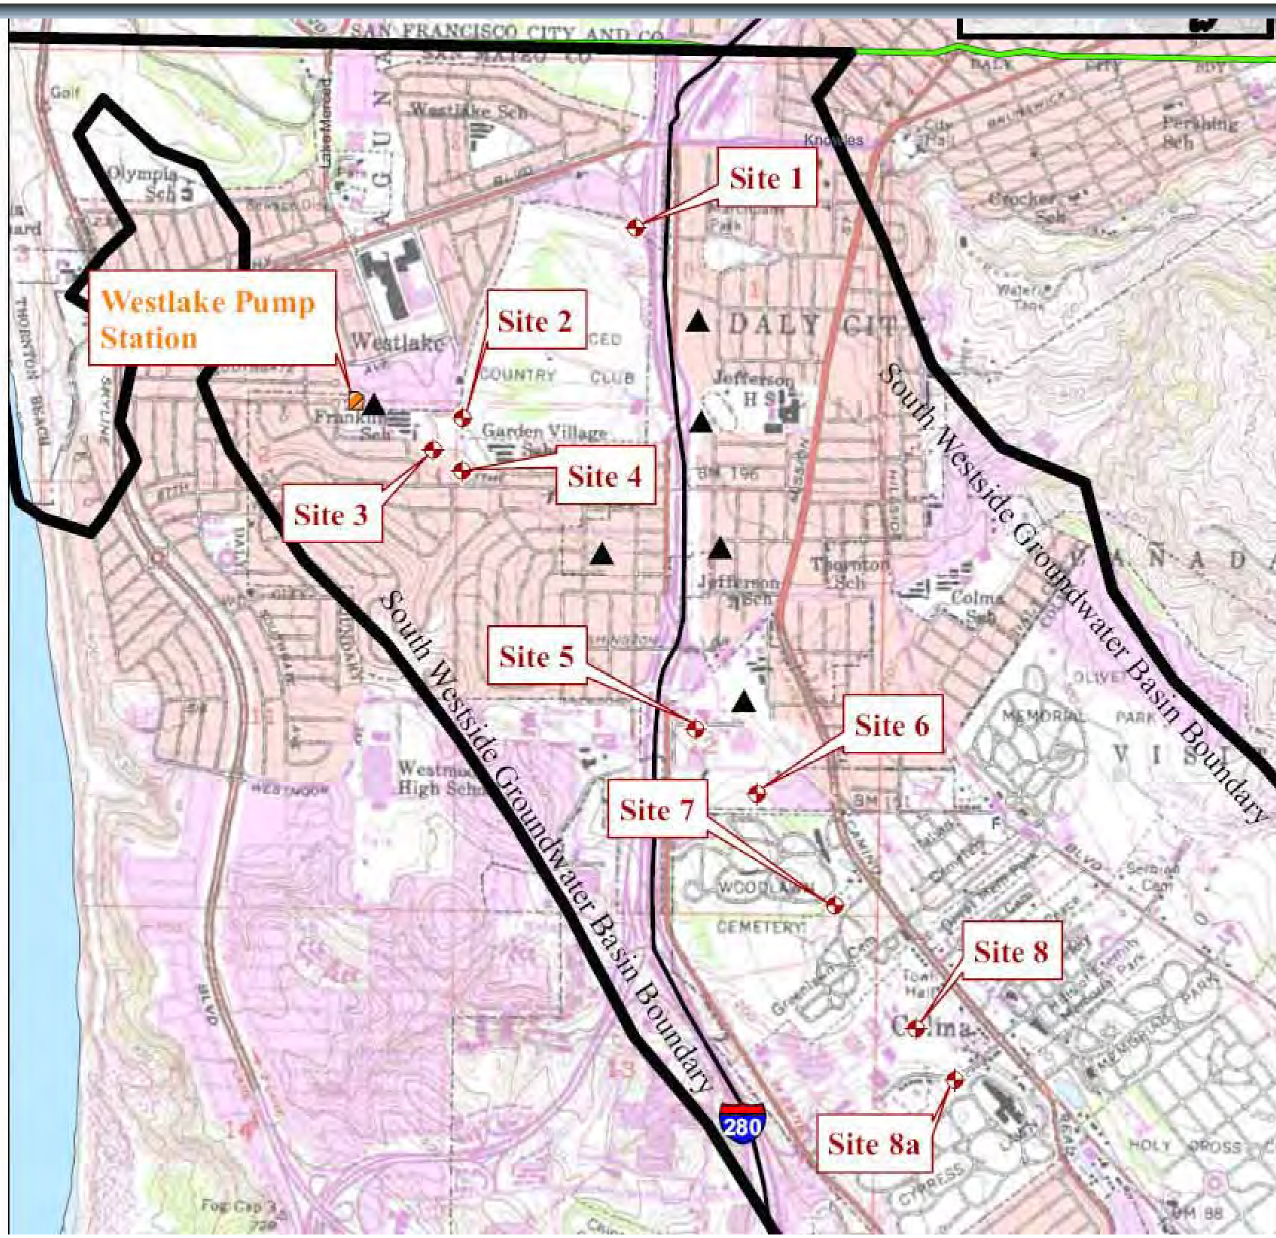
How Would The Project Work?



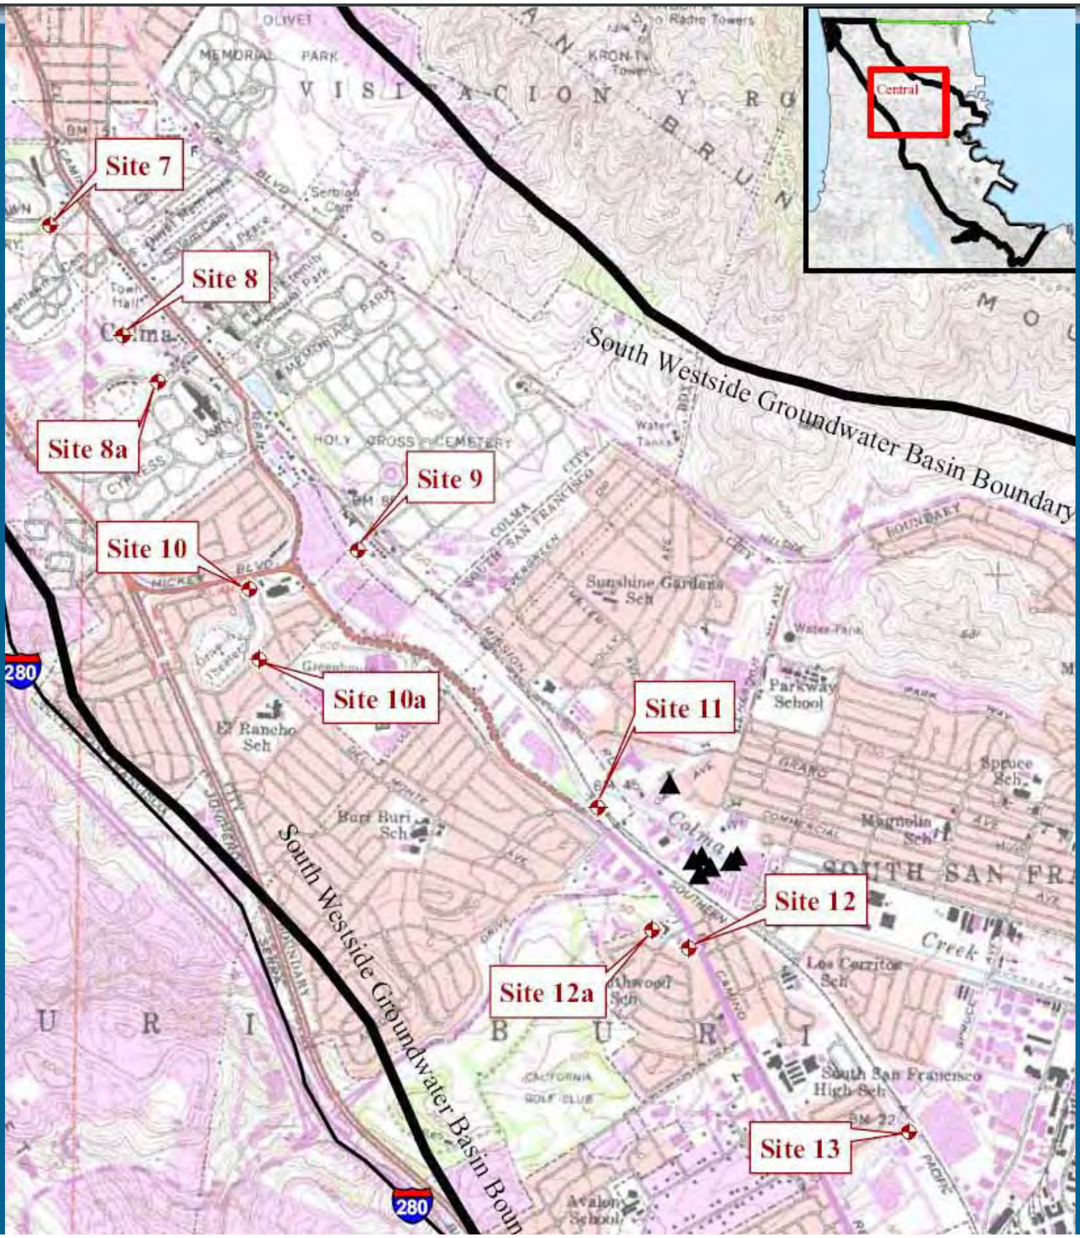
- 48 Potential Well Sites Evaluated
- 19 Sites advanced for EIR
- Up to 16 sites would be developed



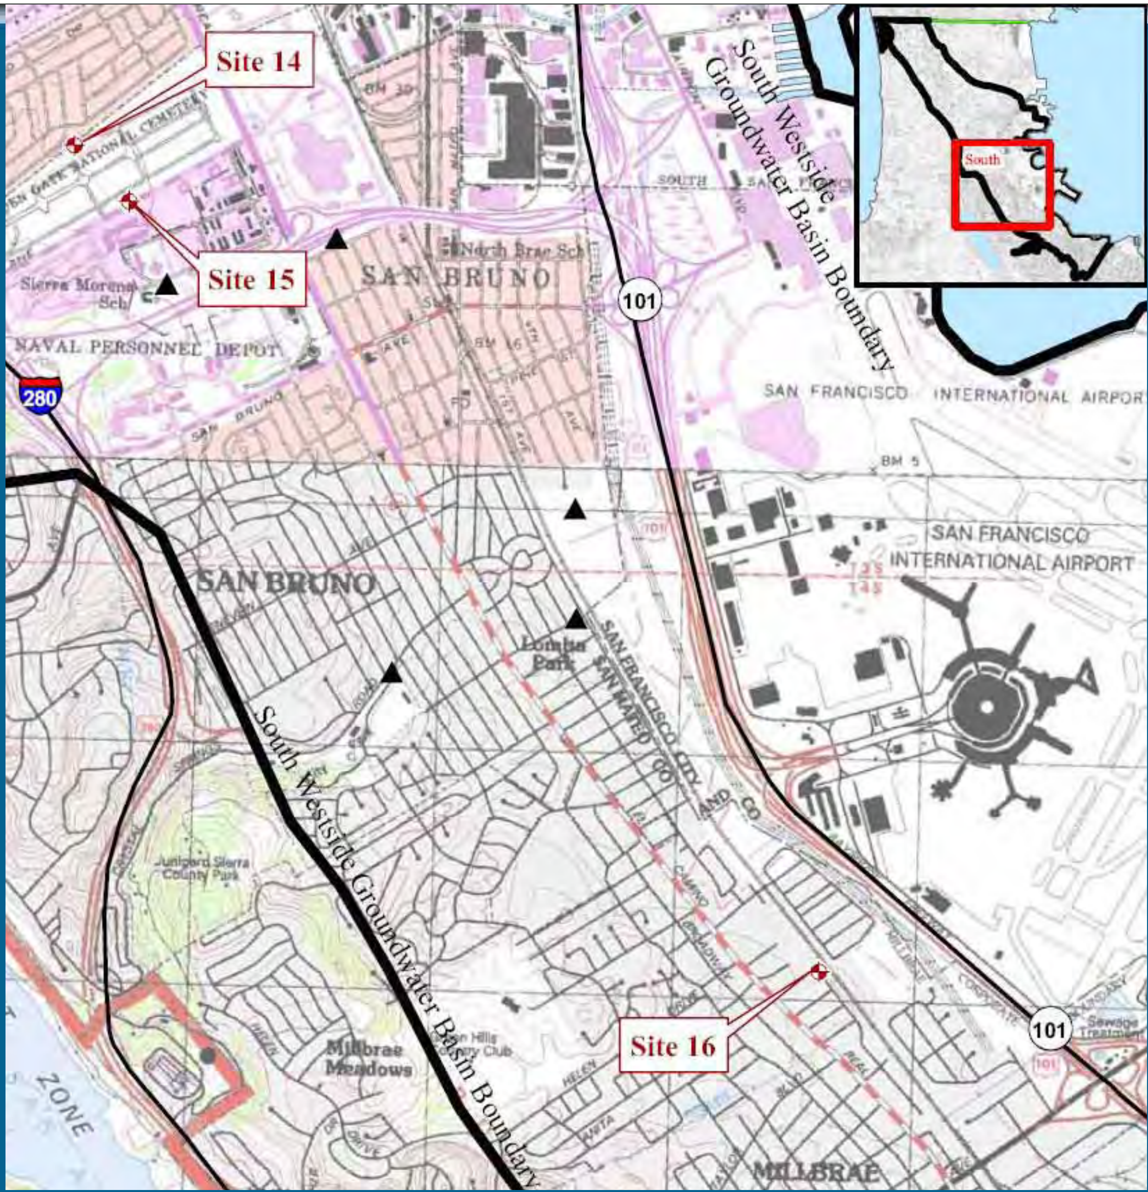
Well Facility Locations (1 of 3)



Well Facility Locations (2 of 3)



Well Facility Locations (3 of 3)



Project Description

- Develop agreements with Daly City, San Bruno, and Cal Water to store 61,000 acre feet of water (approximately 20 billion gallons)
- Develop capacity to pump 7.2 million gallons per day over 7.5 years
- Pump only stored water (an operating committee would be created to monitor the volume of stored and pumped project water)

Project Description

- Construct up to 16 well facilities (including pipelines, etc.)
- Disinfect water per state Department of Public Health requirements
- Provide other treatment if needed (e.g., manganese)
- Connect to Daly City, San Bruno, Cal Water or SFPUC drinking water systems (depending on location).

Ensuring a High Quality Drinking Water

Groundwater Safety

- Groundwater will be in compliance with all California Department of Public Health requirements
- In addition, groundwater will be disinfected before entering the municipal drinking water supply

For over 100 years, groundwater from the Westside Basin has been used for irrigation and drinking water purposes. The cities of Daly City, South San Francisco, and San Bruno currently use groundwater from the Basin as part of their drinking water supply.

Ensuring a high quality drinking water supply

- Monitoring programs will be established to ensure the continued safety and quality of groundwater supplies
- In most cases, groundwater will be blended with imported surface water from the Regional Water System

Typical Site Layout

Sample Well Facility (with Enclosure)

Environmental Review Schedule

- Notice of Preparation – June 24, 2009
- Public Scoping Meeting – July 9, 2009
- Scoping Period Ends – July 28, 2009
- Public Review of Draft EIR – Summer 2010
- Release of Final EIR – Mid 2011
- Certification of Final EIR – Mid 2011

PUBLIC COMMENT

Comment Session Ground Rules

- Submit speaker cards to speak
- Wait until your name is called
- Speak into the microphone and state your name
- Summarize comments verbally and provide more detail in writing
- Use comment forms for more extensive input

Notice of Preparation

June 25, 2009

To: Reviewing Agencies

Re: Regional Groundwater Storage and Recovery Project
SCH# 2009062096

Attached for your review and comment is the Notice of Preparation (NOP) for the Regional Groundwater Storage and Recovery Project draft Environmental Impact Report (EIR).

Responsible agencies must transmit their comments on the scope and content of the NOP, focusing on specific information related to their own statutory responsibility, within 30 days of receipt of the NOP from the Lead Agency. This is a courtesy notice provided by the State Clearinghouse with a reminder for you to comment in a timely manner. We encourage other agencies to also respond to this notice and express their concerns early in the environmental review process.

Please direct your comments to:

Diana Sokolove
City and County of San Francisco
Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103-2479

with a copy to the State Clearinghouse in the Office of Planning and Research. Please refer to the SCH number noted above in all correspondence concerning this project.

If you have any questions about the environmental document review process, please call the State Clearinghouse at (916) 445-0613.

Sincerely,

Scott Morgan
Assistant Deputy Director & Senior Planner, State Clearinghouse

SCH# 2009062096
Project Title Regional Groundwater Storage and Recovery Project
Lead Agency San Francisco, City and County of

Type **NOP** Notice of Preparation

Description NOTE: Review per lead.

The Project would provide potable surface water to the cities of Daly City and San Bruno and the California Water Service Company (Cal Water) (Collectively referred to as Partner Agencies), to be used by these agencies in lieu of pumping groundwater during normal and wet years. The Partner Agencies currently use groundwater as one of the sources of their drinking water supply. The supply would be partially replaced by surface water supplies from the San Francisco Public Utilities Commission (SFPUC) regional water system. The reduction of pumping by Partner Agencies would increase groundwater storage within the South Westside Groundwater Basin. Stored groundwater would be pumped during periods of insufficient surface water supplies: (i.e., dry years).

Various

Project Description: *(please use a separate page if necessary)*
The Project would provide potable surface water to the cities of Daly City and San Bruno and the California Water Service Company (Cal Water) (collectively referred to as Partner Agencies), to be used by these agencies in lieu of pumping groundwater during normal and wet years. The Partner Agencies currently use groundwater as one of the sources of their drinking water supply. The supply would be partially replaced by surface water supplies from the San Francisco Public Utilities Commission (SFPUC) regional water system. The reduction of pumping by Partner Agencies would increase groundwater storage within the South Westside Groundwater Basin. Stored groundwater would be pumped during periods of insufficient surface water supplies (i.e., dry years). (see continuation sheet)

Note: The state Clearinghouse will assign identification numbers for all new projects. If a SCH number already exists for a project (e.g. Notice of Preparation or previous draft document) please fill in.

Ms. Diane Sokolove
City and County of San Francisco
Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Dear Ms. Sokolove:

Regional Groundwater Storage and Recovery – Notice of Preparation (NOP)

Thank you for including the California Department of Transportation (Department) in the environmental review process for the Regional Groundwater Storage and Recovery Project. The following comments are based on the Notice of Preparation.

As lead agency, the San Francisco Planning Department is responsible for all project mitigation, including any needed improvements to State highways. The project's fair share contribution, financing, scheduling, and implementation responsibilities as well as lead agency monitoring should be fully discussed for all proposed mitigation measures and the project's traffic mitigation fees should be specifically identified in the Draft Environmental Impact Report. Any required roadway improvements should be completed prior to issuance of project occupancy permits. An encroachment permit is required when the project involves work in the State's Right of Way (ROW). Therefore, we strongly recommend that the lead agency ensure resolution of the Department's concerns prior to submittal of the encroachment permit application; see the end of this letter for more information regarding the encroachment permit process.

Traffic Impact Study (TIS)

The Department is primarily concerned with impacts to the State Highway System. The proposed project is located adjacent to State facilities. Please ensure that the environmental analysis evaluates the traffic impacts on State facilities by applying the following criteria to determine if a TIS is warranted:

1. The project will generate over 100 peak hour trips assigned to a State highway facility.

2. The project will generate between 50 to 100 peak hour trips assigned to a State highway facility, and the affected highway facilities are experiencing noticeable delay; approaching unstable traffic flow (level of service (LOS) "C" or "D") conditions.

3. The project will generate between 1 to 49 peak hour trips assigned to a State highway facility, and the affected highway facilities are experiencing significant delay; unstable or forced traffic flow (LOS "E" or "F") conditions.

In addition to evaluating peak hour trips for the facility, project vehicle trips and hours of operations should be discussed to determine traffic impacts on roadways. Anticipated street routes for construction vehicles should be identified as well.

We recommend using the Department's "*Guide for the Preparation of Traffic Impact Studies*" for determining which scenarios and methodologies to use in the analysis. It is available at the following website address:
http://www.dot.ca.gov/hq/traffops/developserv/operationalsystems/reports/tisguide.pdf

Cultural Resources
If construction activities are proposed within the State's ROW, the Department requires documented results of a current archaeological record search from the Northwest Information Center (NIC) of the California Historical Resources Information System before an encroachment permit can be issued. Current record searches must be no more than five years old.

The Department requires the records search, and if warranted, a cultural resource study by a qualified, professional archaeologist, to ensure compliance with NEPA (if there is federal action on the project), CEQA, Section 5024.5 of the California Public Resources Code (for state-owned historic resources) and Volume 2 of the Department's "*Standard Environmental Reference*" available at http://www.dot.ca.gov/hq/env/index.htm). Work subject to these requirements includes, but is not limited to: lane widening, channelization, auxiliary lanes, and/or modification of existing features such as slopes, drainage features, curbs, sidewalks and driveways within or adjacent to State ROW.

Transportation Permit
Project work that requires movement of oversized or excessive load vehicles on State facilities requires a transportation permit issued by the Department. To apply, a completed transportation permit application with the determined specific route(s) for the shipper to follow from origin to destination must be submitted to the address below.

Office of Transportation Permits
California DOT Headquarters
P.O. Box 942874
Sacramento, CA 94274-0001

See the following website link for more information:
http://www.dot.ca.gov/hq/traffops/permits/.

Encroachment Permit
Any work or traffic control within the State ROW requires an encroachment permit issued by the Department. Traffic-related mitigation measures will be incorporated into the construction plans during the encroachment permit process. See the following website link for more information: http://www.dot.ca.gov/hq/traffops/developserv/permits/

To apply for an encroachment permit, submit a completed encroachment permit application, environmental documentation, and five (5) sets of plans which clearly indicate State ROW to the address at the top of this letterhead, marked ATTN: Michael Condie, Mail Stop #5E.

Water System Improvement Projects
We encourage the San Francisco Planning Department to coordinate with our Project Manager, Howard Reynolds, at 510-286-7252 for all San Francisco Public Utilities Commission Water System Improvement Program (WSIP) Projects.

Should you have any questions regarding this letter, please contact Lisa Courington of my staff at (510) 286-5505 or via email at lisa.ann.courington@dot.ca.gov.

Sincerely,

Lisa Carboni

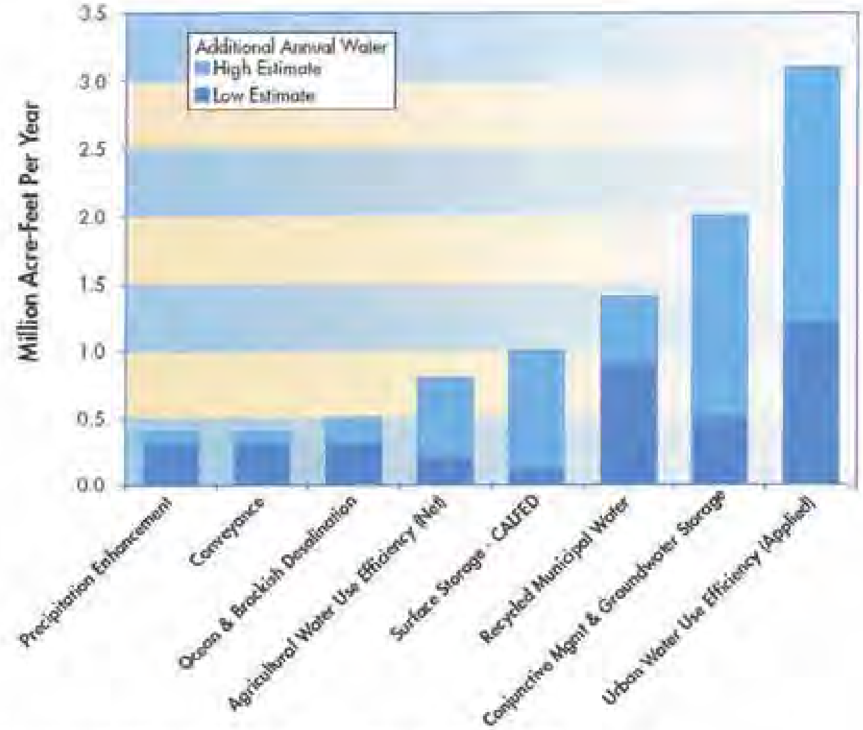
REGIONAL GROUNDWATER STORAGE AND RECOVERY PROJECT

Dear Mr. Wycko:

The Department of Water Resources (DWR) appreciates the opportunity to express support for the concept of San Francisco Public Utilities Commission's (SFPUC) Regional Groundwater Storage and Recovery Project. DWR is aware SFPUC is currently asking for public comments on the above referenced project as SFPUC will soon begin preparation of a Draft Environmental Impact Report (EIR). It is understood specifically that the EIR will document potential impacts resulting from the use of the South Westside Groundwater Basin (basin) as an underground storage reservoir by storing water in the basin during wet periods for subsequent recapture during dry periods.

The intent of this letter is not to comment specifically on any technical aspects of SFPUC's project but rather to recognize the importance of SFPUC's groundwater storage project and other similar groundwater storage projects that meet the State of California's future water supply needs.

The State of California faces a number of challenges to meet its water supply needs in the future, a growing population, changing land use, and environmental and legal restrictions on diversions from the Delta and Colorado River, not to mention the decreasing snow pack and changed hydrology that will result from climate change. A number of approaches will be needed to meet future demands, including water conservation, recycled water, and desalination. As illustrated below, DWR has identified conjunctive management and groundwater storage as one of the resource management strategies in the California Water Plan Update 2005 for making new water supplies available to meet future 2030 year water demands. In fact, conjunctive management and groundwater projects are projected to play a relatively large role in meeting future demands. Groundwater storage projects will provide flexibility as well as water supply reliability improvements on the local, regional, and statewide levels and may equate to an increase in supply up to 2 million acre-feet per year.



Source: *California State Water Plan Update 2005*

DWR strongly supports and has been working aggressively for the last decade to implement additional groundwater storage through locally driven projects such as SFPUC's project. For this reason, DWR will continue to support and look for potential opportunities to work with SFPUC, other state agencies, and project stakeholders to develop successful groundwater storage projects to meet California's water needs. Furthermore, DWR looks forward to the opportunity to review SFPUC's project as outlined in a future EIR.

If you have any questions or wish to discuss this matter further, please contact Trevor Joseph of my staff at (916) 376-9619.

Sincerely,

for Karl P. Winkler, Chief
North Central Region Office

1650 Mission Street, Suite 400
San Francisco, CA 94103

Dear Mr. Wycko:

SUBJECT: Comments on the San Francisco Public Utilities Commission (SFPUC) Regional Groundwater Storage and Recovery Project

Thank you for the opportunity to comment on the Notice of Preparation of an Environmental Impact Report for the SFPUC Regional Groundwater Storage and Recovery Project. Of the various locations noted in the proposal, two sites located in Broadmoor are within the Unincorporated San Mateo County jurisdiction. As such, the SFPUC is required to submit a project description to the San Mateo County Planning Department for review and determination of General Plan conformity pursuant to Government Code Section 65402.

If you have questions, please do not hesitate to contact Melissa Ross at 650/599-1559 or via email at mross@co.sanmateo.ca.us. Thank you again for the opportunity to review and provide comments on the above referenced project and please continue to include the County Planning Department in the processing of the project.

Sincerely,

Melissa Ross, Planner II

San Francisco, CA. 94103

RE: *Regional Groundwater Storage and Recovery Programs, Notice of Preparation of an Environmental Impact Report and Scoping Meeting – Written Comments*

Dear Mr. Wycko,

Thank you for the opportunity to comment on the Regional Groundwater Storage and Recovery Project. Attached are several concerns and questions that the Town of Colma has in regards to the project.

Please contact Brad Donohue, Deputy Director of Public Works at 650-757-8895 or bdonohue@colma.ca.gov or myself at 650-997-8318, if you have any questions.

Sincerely,

Laura Allen
City Manager

c: Honorable Mayor and Members of the City Council
Roger Peters, City Attorney
Andrea Ouse, City Planner
Rick Mao, City Engineer
Diana Sokolove, SF Planner-Senior Planner

The Town of Colma believes that the following questions are relevant to the environmental impacts of the proposed project, as well as reasonable alternatives and mitigation measures relating to the project, and therefore should be analyzed in the proposed Environmental Impact Report (EIR) for the project.

1. What municipalities are located in the overlying lands of the South Westside Groundwater Basin? In particular, is the Town of Colma located in the overlying lands?

2. What rights do the overlying municipalities, including the Town of Colma, and the residents of and property owners within such municipalities have to the use of groundwater in the South West Groundwater Basin (SWGB)? Under California law, an overlying landowner has the right to reasonable use of groundwater located in an underlying basin, subject to reasonable use by other overlying landowners. In addition, landowners may have other rights to the use of groundwater, consisting of appropriative rights (where the landowner has appropriated water from the basin) and prescriptive rights (where the landowner has used the groundwater with knowledge by other groundwater users).

3. Assuming that the overlying municipalities, including the Town of Colma, the residents of and property owners within such municipalities have the right to use groundwater from the SWGB, based on any of the rights described above, would the project have any effect on such groundwater rights, and if so, what effects would be reasonably likely to occur? In particular, would the storage of water in the SWBG during wet periods have any reasonably-foreseeable effects on the Town of Colma and its residents to the use of the groundwater during such periods, and if so, what would be the effects? Would the recapture of water from the SWBG during dry periods have any reasonably-foreseeable effects on the Town of Colma and its residents to the use of the groundwater during these periods, and if so, what would be the effects?

4. If the project has an adverse effect on the Town of Colma, its residents and property owners to the use of groundwater in the SWBG, what provision, if any, does the City of San Francisco, through its planning department or other agencies, plan to take to avoid or minimize such adverse effects? Does the City of San Francisco plan to design the project in a way that avoids or minimizes such effects, and if so, how? If not, does the City of San Francisco plan to provide compensation to those whose rights have been lost or reduced? Does the City of San Francisco plan to take any other action to prevent or minimize the loss or reduction of such rights?

5. The project description in the Notice of Preparation states that California Water Company would provide the water "in its South San Francisco service area . . . ." Does this service area include the Town of Colma, including residential areas located in the Town of Colma? If not, does the project have an adverse environmental effect by reducing the availability of water supplies provided by California Water Company to the Town of Colma and its residents, thus requiring the Town of Colma and its residents to acquire water from other sources? What other sources are available to the Town of Colma and its residents under such circumstances?

6. It is stated that SF Water (SFPUC), Daly City, San Bruno and Cal Water will be the administrative board overseeing the management of the Westside Basin. Please clarify how that was arranged; does the SFPUC intend to include representatives from the neighboring jurisdictions, public representatives and representatives from already existing irrigators (Cemeteries and golf courses)? Why or why not?

7. What will be the purview of the administrative board? Will there be regulations and administrative rules that will govern both the Board and the SWGB? What type and form of notice and how much time will be given to jurisdictions and direct users of the Basin to review and comment on any administrative regulations that may be proposed?

8. How will the baseline data for existing users, such as irrigators, be determined? For existing irrigators who use groundwater for their agriculture or recreational needs, has it been calculated what their daily/monthly and yearly needs are currently. Has there been an assessment of their future needs, for example the expansion of a cemetery site and what impacts that may have (With the expansion more irrigation will be required). Will the current and future water rights of an established pumper be preserved by their current standard? Does the board (Assuming there will be an oversight committee) have a right to dictate how much water can be pumped and will there be limits?

9. When existing wells need to be replaced, what kind of jurisdiction do the water providers have in the replacement procedures? Currently this is permitted by the County, will there be another approval process that will have oversight in this request?

10. Establishing the various base line quantity numbers that has been posted in the Notice of Preparation is critical to current and future assessments. Please provide the data that establishes the bases of:
    An estimate of how much water is currently being stored.
    How it was determined that 61,000 acre foot of groundwater storage is available in the West Side Basin?
    The 7.2 million gallons a day that would be pumped out in dry years, how was that determined?

How long will it take for the aquifer to be replenished or brought to the desired levels.

11. Is the water in the SWGB to be used for the purposes of supplying residential, commercial, agricultural and recreational needs of those who reside over the basin or are there plans to export the water to communities beyond the underlying limits of the SWGB? If so, will this affect the ability of existing users to access more of the resource in the Basin? Will those jurisdictions that are not Partner Agencies be able to review any agreement made with customers not directly over the Basin?

12. Is there a plan to assemble an agreement (Memorandum of Understanding) between the irrigators, water providers and legislative bodies in each jurisdiction to define the various limits and protections for current and future activities?

13. To replenish the aquifer to the assessed amounts stated in various publications (61,000 acre foot), will this harm or potentially damage whatever is above the basin? In turn when the water table is drawn down, will it potentially cause damage?

14. Will any contaminants that lie in stasis above the water table be disturbed with the possible infiltration of groundwater and will the raising of the groundwater table causing contamination of the water?

15. It was stated in the Scoping Meeting (Public Meeting in SSF) that the aquifer is replenished by rain, streams and irrigation through ground peculation. Since irrigation is very similar to rain and rain has a positive effect on replenishing the water table, have irrigation uses been factored into the calculations in replenishing the water table?

16. The project description has been impermissibly piecemealed by omitting the test wells that will be constructed and operated as part of the Regional Groundwater Storage and Recovery Project. In so far as the Project is already defined and proceeding forward to environmental review, it is not tenable to maintain that the test wells are to collect data for a project that may or may not be proposed in the future. Clearly, here the test wells and rest of the Project are all part of the same reasonably foreseeable "project" under CEQA. Thus, the construction impacts of the test wells should be described. How the test wells will be operated should also be discussed. For instance, will excessive rates of pumping be used to test the stability of the underlying aquifers, and will groundwater levels be "drawn down" to evaluate subsurface hydrogeological conditions? Will this result in a cone of depression affecting nearby groundwater users? Also, what will be done with the quantities of water pumped by the test wells?

17. The project description must include information on distribution system extensions necessary to connect Project facilities to existing distribution lines. Where will these lines be placed, and what aesthetic and construction impacts would result? Will there be lengthy street closures or closures of on-street parking along pipeline rights-of-way, affecting traffic, parking, and emergency response, and will economic impacts on local businesses result in indirect impacts on the physical environment?

18. The NOP mentions that "the Westlake Pump Station in Daly City may need to be upgraded and treatment facilities may need to be added to several well facility sites." Pursuant to CEQA, the environmental impacts of both of these additional Project components should be addressed in the EIR (i.e., the full possible extent of the Project's impacts must be analyzed).

BAWSCA

Bay Area Water Supply & Conservation Agency

July 31, 2008

Mr. Bill Wycko
Environmental Review Officer
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Subject: **<u>Case No. 2005.0164E</u> – Response to Notice of Preparation (NOP) of an EIR for the SFPUC Regional Groundwater Storage and Recovery Project**

Dear Mr. Wycko,

Thank you for the opportunity to provide the following comments from the Bay Area Water Supply & Conservation Agency (BAWSCA). BAWSCA represents the interests of the 26 water utilities, including an investor-owned utility and a university, that purchase water on a wholesale basis from the San Francisco Regional Water System. These agencies, in turn, provide water to 1.7 million people, businesses and community organizations in Alameda, Santa Clara and San Mateo Counties. These comments are in response to the Notice of Preparation of an Environmental Impact Report (EIR) for the Regional Groundwater Storage and Recovery project dated June 24, 2009. They are intended as input to the scope and focus of the project.

The comments below follow the report organization and do not reflect the level or priority.

1. **Section 5.2 – Project Objectives**
   The EIR should repeat the clarification made on Page 1, Footnote 1 whenever the 8.5 year design drought cycle is discussed.

2. **Section 5.3 – Proposed Project**
   - The EIR should clarify what rules the SFPUC and Participating Pumpers have agreed to that will govern the operation of the proposed project during wet, normal, and dry periods as well as the development of additional groundwater capability to meet future local water supply reliability needs. The EIR should present the detailed operational strategy for the proposed project, including the individual facilities, along with a detailed hydrologic and environmental impact analysis of the proposed project and associated facilities based upon the known operational strategy.
   - The EIR should address the potential for other users of the basin, who are not participating in this project, to affect the overall storage level in the basin and the amount of water potentially available for withdrawal under this project. The EIR should discuss what mechanisms can be implemented to protect the Program Storage against withdrawal by other non-participating pumpers.

155 Bovet Road, Suite 302 • San Mateo, CA 94402 • *ph* 650 349 3000 • *fx* 650 349 8395 • www.bawsca.org

3. **Section 5.3.1 – Groundwater Storage and Recovery**
   - The NOP states "This new dry-year water supply would be made available to both the Partner Agencies and SFPUC wholesale customer under the terms of the Shortage Allocation Plan between the SFPUC and its wholesale customers." The EIR should clarify exactly how this new dry-year water supply would be incorporated into that Plan. If the intent is that the available Program Storage, as quantified by the SFPUC Storage Account, will be taken into consideration by the SFPUC when determining how much water is available for delivery to customer and whether a shortage condition exists, then the EIR should provide this clarity.
   - The EIR should address how the Program Storage and associated project facilities might be used during an emergency, what rules would be applied to such operations, and who the beneficiaries would potentially be.

4. **Section 5.3.2 – Production Wells and Associated Facilities**
   - The EIR should discuss the reason(s) for providing disinfection facilities at each well as disinfection is not necessarily required under Title 22 of the California Code of Regulations.
   - The EIR should specify the type of disinfection method to be used (chlorine or chloramines) and discuss any blending impacts or water quality compatibility issues.

5. **Section 5.3.4 – Operations and Maintenance**
   - The EIR should provide the water supply availability criteria to be used to determine the conditions of a "normal", "wet", and "dry" year associated with the proposed conjunctive use operation. Also, the definition of "excess surface water" that determines the amount of reduced groundwater pumping in normal and wet years needs to be provided.
   - The EIR should define the methods to determine the amount of groundwater in the storage account at any point in time. Also, the basis for estimating underground losses of stored water that is not subsequently available for recapture needs to be explained.

6. **Section 6.0 – Permits and Approvals Required**
   The California Department of Public Health (CDPH) should be added to the list of permitting agencies.

7. **Section 9.1.3 – Hydrology and Water Quality**
   - It is indicated in the documentation for this project that Drinking Water Source Assessments will be performed during pre-design. Will these assessments be available for use in the EIR analysis?
   - The EIR should include a groundwater recovery assessment.
   - The EIR should discuss the lake level management plan for Lake Merced.
   - The EIR should include the site-specific water quality testing data which is required in the pre-design.

- The EIR should include an assessment to determine the ability to meet water quality goals when blending under the planned operational scheme. Project documentation indicates this will be verified from water samples collected from the test wells in the pre-design phase. Will there be sufficient information available at the time of the EIR analysis to confirm that blending is a viable method to achieve water quality goals?
- The EIR should provide the details of the long term monitoring program which will be used to assess changes in local groundwater quality and levels within the South Westside Groundwater Basin as a whole. This program should include the development of a best practices plan to protect the groundwater basin if not already developed.
- Is there any plan for using recycled water in the groundwater basin? If so, then an assessment of potential impacts of this practice should be performed.

8. **Section 9.2 – Alternatives**
If there are alternatives that consider different well locations than those listed in Table 1, the EIR should discuss the siting criteria used to select an alternative well site.

Thank you for the opportunity to provide these comments on the Notice of Preparation dated June 24, 2009 regarding the Regional Groundwater Storage and Recovery project. If you have any questions, please contact me at (650) 349-3000.

Sincerely,

Re: Regional Groundwater Storage and Recovery Project – Scoping Comments

Dear Mr. Wycko:

This law firm represents the Green Hills Country Club, the Lake Merced Golf Club, the Olympic Club, and the San Francisco Golf Club (the Clubs) with regard to certain water-related matters, including the Regional Groundwater Storage and Recovery Project (Project) being proposed by the San Francisco Public Utilities Commission. This letter constitutes scoping comments by the Clubs for the anticipated environmental impact report (EIR) that will be prepared for the Project.

The Clubs are interested in the proposed Project because they each pump groundwater from the South Westside Basin Groundwater Basin (Aquifer) for a portion of their irrigation water supply, a recognized beneficial use of the available groundwater resource. As overlying property owners, the Clubs each have the legal right to pump that amount of water reasonably needed for their use for irrigation of their property, and their rights are protected against injury by California law. The Clubs recognize the efforts being made by the SFPUC to improve water supplies and water management for the utilities and communities in the region, including increased use of groundwater resources. The Clubs do not oppose the proposed Project, but believe that it should be the subject of full evaluation in the EIR before any portion of it is approved by the SFPUC. The Clubs' comments set forth below should be among the matters taken into account in preparing the EIR.

As the Clubs understand the proposed Project, the SFPUC will deliver imported Hetch Hetchy surface water supplies to municipal water utilities in Daly City, San Bruno, and other communities which pump all or a portion of their water supply from the Aquifer, in an effort to take the place of groundwater during normal and wet years. Approximately 5.4 million gallons per day (mgd) of surface supplies will be substituted for the approximately 6.7 mgd of groundwater that is currently extracted from the Aquifer by the municipal utilities. Irrigation well users will not get substitute supplies.

In dry years, the SFPUC would plan on extracting up to 7.2 mgd from the presumably fuller Aquifer, in addition to the 6.7 mgd that would be extracted by the municipal utilities which are the SFPUC's "partners" in the proposed Project. In other words, although current extractions from the Aquifer in dry years are at the rate of approximately 6.7 mgd, if the Project is approved and fully implemented, a total of 13.9 mgd of groundwater will be pumped. The SFPUC plans are for this higher rate of pumping to be made possible by removal of the increment of additional water that remained in the Aquifer rather than being pumped during the normal to wet years when surface water is provided to the municipal partners. This form of storage and recovery of water from a groundwater basin is commonly called "in-lieu recharge" or "conjunctive use."

Overall, the Clubs' understanding is that the SFPUC's fundamental Project idea is to utilize approximately 60,000 acre-feet (AF) of the estimated 70,000 AF of available groundwater storage in the Aquifer. In addition, the SFPUC apparently wishes to "recover" the estimated 15,000 AF which it asserts has been "stored" during a "pilot study" of this in-lieu process; that study began in approximately 2002. The Clubs understand that the proposed Project includes construction of up to sixteen new extraction wells from 19 preferred sites, which will be spread from Daly City to Millbrae, generally along El Camino Real (Hwy 82). No injection or recharge "spreading" of groundwater is planned as part of this Project. The Project will also include a number of monitoring wells, some of which have already been constructed.

Approximately three test wells will apparently be constructed in 2009-2010, and the SFPUC staff has indicated they will not be part of the EIR. Instead those test wells are deemed by the SFPUC to be categorically exempt from the need to do more detailed environmental documentation. However, the Clubs understand that the test wells will be constructed so as to function as operational wells (and will be at planned extraction well locations), so they will be more fully examined as part of the Project CEQA process. The Clubs believe that it is appropriate to include the test wells in the EIR so that they cannot be placed in full operation until the EIR is certified and the Project is approved.

The Clubs see the following as potentially important issues that should be addressed in the EIR:

1. Protection of Existing Water Rights – The EIR needs to address protection of existing overlying rights and protection of any existing overlying rights that are not currently utilized due to the use of recycled water for irrigation where that is done in areas served by the Aquifer. If the SFPUC seeks to recover the 15,000 AF they have already "stored," the EIR should indicate how the interests of

overlying owners will be protected—i.e., how will the SFPUC assure other pumpers that their water rights will not be impaired by this excess pumping?

2. Protection of Water Quality - Both extremes of this situation (high water levels and low water levels in the Aquifer) can negatively impact water quality. Higher water levels may mobilize minerals and potential contaminants that have been previously stationary. Conversely, the potential for water levels to decline, even temporarily, as a result of the dry year pumping may negatively impact water quality by concentrating contaminants and minerals. There may also be potential for mixing of waters (and minerals) that may not otherwise have occurred, which could be a cause for concern and should be analyzed..

3. Potential Impacts on Wells – Since historic pumping by the municipal utilities (and to a more limited degree by irrigators) has lowered water levels in the Aquifer, one challenge of the Project and especially the EIR is to analyze the potential impacts of refilling the Aquifer in the event of a series of wet or normal years. There is potential for negative impacts to the production wells of pumpers, including the Clubs, particularly during dry years. The Clubs understand that the initial modeling that has been done suggests that only a few municipal wells (1930's-vintage California Water Service Company wells) are expected to be impacted, but that modeling did not address impacts on irrigators. Should water levels be depressed below the screened intervals of the well casings, there is a possibility of long-term well damage. Energy costs for irrigation users of the Aquifer should also be analyzed. Adverse impacts on private wells may require mitigation by the SFPUC, and this needs to be analyzed and disclosed.

4. Location of Wells (Well Interference) - The locations of the new extraction wells proposed by the SFPUC, and any new wells planned by their municipal partners, need to be fully disclosed and analyzed, and included in the draft EIR, with detailed maps. The potential for direct impacts from the effects of the extraction wells is real and needs careful analysis. The results of the analysis to be determined by mutual interference modeling needs to be fully disclosed and analyzed in the EIR and the mitigation plan.

5. Available Aquifer Storage – In all aquifer storage and recovery projects, and particularly in the case of an in-lieu project such as this, there is always the possibility that the ratio of "stored" to future extracted water is not actually or even close to 1:1. There is always the potential for new users. There is also the potential that the "stored" water is simply lost (i.e., the stored water may not stay within the Aquifer, or at least within that portion of it utilized). The actual "usable" available storage may also not be accurate (i.e. the 70,000 AF estimate).

This issue is fraught with the potential for dispute, as many groundwater users experienced in the long fight over the Santa Maria Basin. Careful environmental and technical analysis of the actual storage capacity and the effects of its use are needed before the proposed Project is approved. None of the interested parties would be benefited if inadequate analysis leads to a project that results in conflict and controversy, particularly if it leads to the possibility of a basin adjudication.

6. Cumulative Impacts – The EIR needs to fully analyze the impacts of the proposed Project and other groundwater-related projects in the area, including but not limited to the SFPUC's proposed Lake level restoration project for Lake Merced, the project to pump groundwater at production rates from the North Westside Basin, and the variety of recycled water projects proposed in various portions of the lands overlying the Aquifer. Stormwater management projects being considered in the area, particularly by Daly City, also need to be taken into account, particularly to the extent they may involve detention basins. All of these related types of projects should be considered as elements of a comprehensive integrated water resources management approach to deal with the many challenges facing the SFPUC and the other water agencies in the area

The Clubs appreciate the opportunity to submit these comments on the proposed Project during the scoping phase. The Clubs hope to have the opportunity to participate in future phases of the Project, including possibly serving on an advisory committee of groundwater users if one is formed. If you have any questions about this letter, please contact me or Douglas E. Coty at the address and telephone number shown above.

Very truly yours,

Robert B. Maddow

--- Case No. 2005.0164E

Dear Mr. Wycho:

I was dismayed to find no mention of Lake Merced in the above referenced document.
Rather than supply additional comments I will simple say that I agree with the comments made by Mr. Cadagan for the Committee to Save Lake Merced.
Thank you considering these comments and working to ensure an adequate CEQA document and project.
Sincerely,

For California Trout

Re: Regional Groundwater Storage and Recovery Project Scoping Comments --- Case No. 2005.0164E

Dear Mr. Wycho:

What follows are the comments of the Committee to Save Lake Merced (the "Committee") on the June 24, 2009 Notice of Preparation (and Project Description and related materials) of an Environmental Impact Report ("EIR") for the San Francisco Public Utilities Commission's Groundwater Storage and Recovery Project (the "Project"). The Committee is a coalition of users of Lake Merced formed in 1993 to address the declining water levels in the lake. The Committee has since 1993 remained active in the efforts to permanently reverse those declining water levels and anticipates remaining active until a final resolution of the lake level issue is reached. Thus, our comments here are primarily directed at matters that relate to Lake Merced water levels. However, we anticipate that one or more organizations concerned with issues affecting the Tuolumne River will also comment on the scope of the EIR for the Project. We are firm supporters of the goals of those organizations and in no fashion do we intend that our comments be inconsistent with the goals of those concerned with the health and welfare of the Tuolumne River.

The Project is a conjunctive use project and, as the NOP points out, was listed as the "Conjunctive Use Project" in the SFPUC's Water System Improvement Program and the related Program Environmental Impact Report. The Committee is fully supportive of conjunctive use of water, but also mindful of the old adage that "the devil is in the details". In this case it can't be determined if there is a devil in the details because there are far too few details in the project description found in the NOP. Some of the more important matters that need to be in the project description before meaningful environmental analysis can be done appear in the numbered paragraphs below.

The primary purpose of an EIR is to "identify significant effects on the environment of a project". The NOP lists in Section 9.1 some of the environmental issues to be addressed, including land use; geology, etc; hydrology and water quality; biological resources; cultural resources; traffic,etc; noise and vibration; and recreational resources. Surprisingly, nowhere in Section 9 of the NOP (or elsewhere in the project description or related material presented at the July 9 scoping meeting) is mention made whatsoever of "Lake Merced" or the "Tuolumne River". It is in those two bodies of water that the potentially truly significant negative environmental effects of the Project might materialize. Being specifically interested in Lake Merced, the Committee notes that it is fairly well acknowledged that a significant contributing factor to the environmentally damaging decline in lake levels during the 80's was excessive pumping from the Westside Basin aquifer. That resulted in an overdraft condition in the aquifer. The Committee does not find comfort in the material currently available that excessive aquifer pumping and resultant aquifer overdraft might not result from operation of the Project thereby causing significant and unnecessary harm to the environment.

It is fundamental to CEQA that an EIR must be prepared with "a sufficient degree of analysis to provide decision makers with information which enables them to make a decision which intelligently takes account of environmental consequences." CEQA Guidelines ¶ 15151. No citation should be needed for the proposition that an EIR cannot meet that test if the description of the project that is the subject of the EIR is fundamentally inadequate. It is possible that SFPUC plans to amplify the project description after the deadline for scoping comments has passed. That would seem inconsistent with the spirit of the scoping process and, in this case, the requirement that at least one scoping meeting be held in connection with projects of statewide, regional or areawide significance. CEQA Guidelines ¶ 15082(ç)(1). In other words, what is the point in having a mandatory scoping procedure if the project description in existence at the time of the scoping meeting and during the scoping comment period is so lacking in basic information?

Based on the foregoing, and taking into the specific comments below on the inadequacy of the detail in the project description, the Committee respectfully submits that the NOP should be withdrawn at this time and reissued only when an adequately detailed project description is submitted by the SFPUC.

A second important purpose of an EIR is to identify alternatives to the project. One possible alternative (maybe better characterized as a "supplement") would be to add as a project feature the injection of stormwater and/or recycled water to the aquifer. Upon informal preliminary inquiry in this regard we were told that geological conditions in the area do not lend themselves to effective use of injection wells. This issue needs to be examined (and discussed in the EIR) in much greater detail, including consideration of using the soon-to-be-made-public groundwater model to determine optimum locations for injecting stormwater and/or recycled water.

We submit the following specific comments, most of which are consistent with our belief that the existing project description in inadequate to allow for meaningful CEQA review in an EIR.

1. The project description lacks definitions of critical terms such as "excess surface water" (¶1.0; p.1), "dry, normal and wet" years (throughout the project description); "sufficient surface water supplies" (¶5.3.1; p.9).

2. The project description lacks adequate information regarding the aquifer in question to give meaning and context to the stated project purposes (¶5.2; p.8). It is stated more than once (e.g. ¶5. 3.1; p.10) that storage in the aquifer will be increased by 61,000 AF "eventually". But neither the total capacity or current storage volume in the aquifer (or relevant portion of the larger Westside Basin aquifer) is given. This project relates to just the South Westside Groundwater Basin which is a part of the larger Westside Groundwater Basin. An earlier study of the entire Westside Groundwater Basin estimated that "on the order of 75,000 acre-feet of available storage" would be available for possible conjunctive use. Luhdorff and Scalmanini, Update of the Conceptualization of the Lake-Aquifer System: Westside Ground-Water Basin, April 2004. These numbers may possibly be reconcilable, but it would be essential for those doing the current environmental study to have up-to-date information on total capacity of the South Westside Groundwater Basin, its current storage situation, and unused capacity for future conjunctive use storage.

3. Related to paragraph 2 immediately above is that fact that SFPUC has plans for groundwater development in the North Westside Groundwater Basin. The current project description should spell out how these two seemingly closely related projects are being integrated.

4. Many of the answers to the specific issues raised above may ultimately be found in the "groundwater storage and recovery agreement" cryptically mentioned in ¶5.3.1 (p.10) and slightly more prominently mentioned in footnote 5 to ¶5.3.4 (p.20). If that agreement is intended to spell out critical questions such as the missing definitions and even more basic questions ---- such as whether pumping in dry years may occur before recharge has occurred ---- then that agreement should be prepared and publicly disclosed before preparation of the EIR. (As noted above, the scoping process should occur after, not before, those critical details are revealed.)

5. The Committee cannot keep current on evolving CEQA law regarding the need to consider climate change in EIRs under CEQA. Regardless of the current state of the law, in this instance it seems essential that climate change be considered in detail given that the project is partially based on the premise that there will be undefined "excess" surface water (presumably referring to Tuolumne River water --- 85% of SFPUC's surface supply) available in the undefined "normal and wet years".

Respectfully Submitted,

Committee to Save Lake Merced

Re: Regional Groundwater Storage and Recovery Project Scoping Comments

Dear Mr. Wycko:

The Tuolumne River Trust appreciates the opportunity to comment on the Notice of Preparation of an Environmental Impact Report for the Groundwater Storage and Recovery Project (Case No. 2005.0164E).

The purpose of the Project is to further the use of the South Westside Groundwater Basin as an underground storage reservoir by storing water in the basin during wet periods for subsequent recapture during dry periods. The dry year water supply would be made available to the cities of Daly City and San Bruno, the California Water Company in its South San Francisco service area, and SFPUC wholesale water customers.

In general, the Tuolumne River Trust supports the concept of cooperative management of surface water and groundwater to optimize the water demand and supply balance. However, we have concerns that this project could harm the Tuolumne River by increasing diversions in normal and wet years.

Need to Study Impacts on the Tuolumne River

Figure 5 in the Notice of Preparation (Source of Water Supply for Partner Agencies) suggests that the SFPUC would provide an additional 5.4 million gallons of surface water per day (mgd) to its customers in normal and wet years to enable them to reduce groundwater pumping by an equal amount. The EIR needs to identify the source(s) of this additional surface water. It also should define wet, normal and dry years. Assuming most of the additional 5.4 mgd is expected to come from the Tuolumne River, the impacts of increasing diversions should be studied in the Project EIR.

Currently, 60% of the Tuolumne River is used for agricultural and urban uses, and even more water is diverted, causing significant impacts to the river ecosystem. For example, the population of Chinook salmon has declined from more than 100,000 individuals per year prior to dam building, to 18,000 in 2000, to less than 500 in 2008. In its comment letter on the Water System Improvement Program (WSIP) DPEIR dated October 1, 2007, the California Department of Fish and Game (CDFG) stated that lack of adequate instream flows was the primary cause of the decline in anadromous fish. Diverting more water from the Tuolumne would only exacerbate this problem.

The WSIP PEIR attempted to address the impacts on salmon and steelhead of diverting more water from the Tuolumne, however, the analysis was wholly inadequate. The Tuolumne River Trust and other conservation organizations did not issue a legal challenge to the PEIR because we did not want to delay the seismic upgrades to the Hetch Hetchy Water System.

New information about potential impacts to the Tuolumne River from increasing diversions should be included in the CEQA analysis for the Groundwater Storage and Recovery Project. For example, the SFPUC is currently conducting a study of biological resources in the stretch of the Tuolumne downstream of the Hetch Hetchy Reservoir to meet a condition of the 1987 Kirkwood Powerhouse Agreement. Because the study was not completed in time to be included in the WSIP PEIR, it is important that the results of this study be considered as soon as possible. This study is expected to be completed by the end of 2009.

On January 15, 2009, CDFG submitted comments on the San Joaquin Pipeline System Project. They stated:

> "We are concerned, however, that the addition of a new pipeline segment will provide conveyance capacity for increased diversions from the Tuolumne watershed. "To contribute toward meeting the overall program objectives of the WSIP, the SFPUC has designed the SJPL System Project to meet current and future water demand" (Pg. 1-2, DEIR). This implies the SJPL will be integral either now or in the future for conveying additional water supplies which would likely include diversions of about two million gallons per day (mgd) over existing conditions from the Tuolumne River. Be advised that for any activity that will divert or obstruct the natural flow…DFG may require a Lake and Streambed Alteration Agreement (LSAA), pursuant to Section 1600 et seq. of the Fish and Game Code, with the applicant."

CDFG went on to say:

> "In those documents (CDFG comments on the WSIP PEIR), we described in detail the critical and dire condition of native salmonids in the Tuolumne River. We thoroughly outlined the relationship between in-stream flows and native salmonid productivity, as well a the need for decreased, rather than increased, Tuolumne River diversions to sustain native salmonid populations at *high risk of extinction*. Increased diversions of two mgd would also likely worsen conditions for other fish species in the Tuolumne River, and would likely add to cumulative impacts to water quality of the San Joaquin River, that may further impact sensitive species including federally threatened steelhead (see Zimmerman et al. 2008), State and federally endangered Delta smelt (Hypomesus transpacificus), federally threatened southern distinct population segment (DPS) green sturgeon (Acipenser medirostris), and the State candidate longfin smelt (Spirinchus thaleichthys), currently petitioned for endangered status. DFG continues to respectfully request SFPUC consider all other

potential options for meeting increased customer demand until and after the year 2018."

These comments should be addressed in the Project EIR for the Groundwater Storage and Recovery Project.

It should be noted that wet years do not result in "wasted" water. Wet years can provide better flows for juvenile salmon and steelhead, enabling them to get flushed out into the Bay and Ocean in higher numbers. In big water years, such as 1982/83 and 1997/98, the two reservoirs on the Tuolumne River filled to capacity, causing spillage over the dams. As a result of the increased instream flows, the numbers of adult salmon and steelhead returning three years later increased dramatically. However, in 1994, despite the relative abundance of water, most of the River's flow was captured in the two reservoirs to fill them after several years of drought (see attached graph). As a result, the number of returning adult salmon three years later was much smaller than would otherwise have been expected.

The EIR for the Groundwater Storage and Recovery Project should study the impacts of diverting additional water from the Tuolumne on fish populations even in wet and normal years.

Furthermore, requirements for instream flows in the lower Tuolumne are likely to increase as a result of the FERC relicensing process that will begin in 2011 and be completed in 2016.

A recent FERC order on a rehearing request for the 1995 FERC Settlement Agreement acknowledged the existence of steelhead in the lower Tuolumne and the need for them to be addressed. It found that interim measures may be required prior to relicensing. It also determined that within four years an instream flow of 4,000 cfs in the spring would be needed for study purposes and that the instream flow study, including a plan for a temperature model, be developed by MID and TID in consultation with NMFS, FWS and CDFG.

This, and future FERC actions, must be considered in the CEQA analysis for the Groundwater Storage and Recovery Project.

Need to Study the Potential for Using Stormwater Runoff and/or Recycled Water to Enhance Recharge of the Groundwater Basin

In response to CDFG's request that "SFPUC consider all other potential options for meeting increased customer demand," the EIR for the Groundwater Storage and Recovery Project should study the potential for using stormwater runoff and/or recycled water to enhance the recharge of the groundwater basin. This would enable a higher sustainable rate of groundwater use in normal and wet years, thus reducing or eliminating increased diversions from the Tuolumne River.

We believe our concerns are shared by the SFPUC Commission and the San Francisco Planning Commission. SFPUC Resolution No. 08-0200, which approved the WSIP on October 30, 2008, states:

"Further resolved, the San Francisco Public Utilities Commission shall set aggressive water conservation and recycling goals, shall bring short and long-term conservation, recycling and groundwater programs on line at the earliest possible time, and shall undertake every effort to reduce demand and any further diversions from the San Francisco Public Utilities Commission watersheds…"

In a letter dated December 18, 2008 to SFPUC President, Ann Moller Caen and SFPUC General Manager, Ed Harrington, the San Francisco Planning Commission wrote:

"As you know, the Tuolumne River is a precious resource and the City and County of San Francisco should continue to protect it. Thus, the Commission urges the SFPUC to continue to find alternative ways to provide water supply to the service area that do not involve withdrawing additional water off the Tuolumne River."

Thank you for considering our comments.

Sincerely,

Peter Drekmeier

Sent by email to diana.sokolove@sfgov.org submitted at 3:20 PM

Subject: South Westside Groundwater Basin EIR Scoping

Dear Mr. Wycko:

Restore Hetch Hetchy appreciates the opportunity to provide scoping input for the SFPUC WSIP Regional Groundwater Storage and Recovery Project EIR, Case No. 2005:0164E.

The use of this aquifer for domestic water supply during the design drought is good conjunctive-use, but the concept of replacing the present well water being pumping with surface supply to allow replenishment naturally during normal and wet years without listing the source of that surface water gives the impression that other watersheds will suffer impacts, which are not going to be addressed in this EIR. This is a serious omission that the EIR must address. Because you did not mention the specific source of the "surface water, when available" in your current Notice or Description, immediately makes those involved with the SFPUC source watersheds think the worst—that more water will be drawn from these watersheds for this project. The fear is that offsetting replenishment surface flow were not presented nor mitigation provided for in your department's 2008 PEIR for the WSIP, Case No. 2005.0159E referenced in your Description. They would want those sources to be acknowledged and their impacts shown and mitigation provided for in this project EIR. It would be a mistake not to do so if those assumptions are true.

To calm everyone we ask that you present a water balance in this EIR stating the source of this replacement water proposed and giving a

Tuolumne River at Moccasin in 2018 on a five-year rolling average; the same from Alameda Creek watershed to the Sunol Water Treatment Plant; from the Peninsular watersheds to Tracy WTP; from groundwater pumping inputs; purchases from other water suppliers; amount of Tuolumne River water put into and recovered from San Antonio Reservoir; amount of Tuolumne River diversion put into and recovered from Crystal Springs Reservoir; amount of Tuolumne River water put into and recovered from Pulgas Reservoir; amount traded to and from other water agencies (e.g. EBMUD); amount purchased from other agencies and delivered through the South Bay Aqueduct; the amount rejected from each of the two WTP as part of their normal operation; amount rejected at Livermore Lab water treatment facility; amount rejected by backwash from well water filtration; the amount sold to BAWSCA including "surface water, when available" "in lieu of pumping ground water" for this aquifer project as a separate item; sales within the City of SF; that sold to Lawrence Livermore Lab; that sold to GE nuclear power generation near Sunol; amount sold to or purchased from other government agencies not already included; evaporation from WTPs and storage; transmission losses; losses from meter failure in SF (delivered but not billed or over billed); accretions; water main flushing; fire fighting use and hydrant testing; and system operating spills and releases. The amount sold to GCSD and that served to Moccasin and Early Intake should be stated as separate diversions. Input flows will equal sales and outputs. The amount of 223 mgd total sales goal by 2018 was stated to your Planning Commission for the PEIR on Oct 30, 2008 by SFPUC General Manager, Ed Harrington, during the decision meeting for Case No. 2005.0159E. That amount has never appeared in print and this is the place for it to be stated and explained. That water balance will let everyone know where the surface water replacement flow is coming from for this project. Our expectation is that this water balance will show the well water replacement flow is part of the 223 mgd five-year rolling average goal for 2018.

A second reason we ask for this water balance is for you to explain how the goal of total sales got from 217.3 mgd (calculated from Figure 2.4 on page 2-18 of the DPEIR) to 223 mgd that the Commission accepted. Two mgd of the increase was noted in the WSIP Revision supplement (Chapter 13, Table 13.2, in the Phased WSIP column at page 13-13), but the purpose or reason for it was never given in print, nor was the other 3.7 mgd additional Tuolumne River diversion explained in print that was added by the General Manager just before October 30. This extra amount also needs to be explained. This EIR is the place to explain these increases as well as the source for the 4.5 mgd replacement surface (flow calculated from Figure 5 page 21 of this Description). Is the 4.5 mgd replacement flow part of the 223 mgd rolling average total sales as we expect? Or do you plan to purchase this replacement water from another source? A water balance will answer all these questions and restore our faith in your EIR process.

Although Lake Merced is just north of the study area of the South Westside Groundwater Basin, please discuss the "potential for flow from shallow aquifer/lake system toward the underlying

aquifer from which nearby production wells withdraw water" in the South Westside Groundwater Basin south of Lake Merced (quote from DPEIR page 5.6-15 paragraph two). Also discuss using recycled water, and urban storm runoff after the first flushing rain as sources to raise the level in Lake Merced for this recharge purpose.

The DPEIR lists several golf courses located atop this aquifer that are successfully using recycled water for irrigation (DPEIR page 5.6-8). Discuss the impact on aquifer recovery from conversion to using recycled water for additional golf courses and other irrigated landscapes located over this aquifer that still pump from this aquifer or use system water for irrigation.

Discuss the rate of aquifer refilling as related to less pumping and use of recycled water for irrigation above the aquifer.

Discuss what would be necessary to recharge more of the 75,000 acre feet vacant storage available in this aquifer for drought use (DPEIR p 5.6-25) and the time to accomplish refilling.

Explain how the high nitrate and manganese concentrations in water from this aquifer will be handled during drought when about 7.2 mgd will be added to the diminished surface supply (volume reference is from Section 5.3.2 of this Description and the minerals noted are in section 5.6.1.8 in DPEIR). Will wellhead treatment be used to accomplish reduction of these two chemicals or will blending with system water take care of these problems?

If this is a"Regional" Project, why is the North Basis not included?

Please acknowledging this submission from us at jdmack@jps.net Please mail the author a hard copy of this DEIR and FEIR when each is available.

Sincerely,

Bob Hackamack, P.E.

RE: RHH submissions to Regional Groundwater Storge & Recovery Project scopinng

Diana: Thanks for your reassuring response that my comments reached you before the deadline. You can tell from the typos in the subject line that I was worried that things might go wrong.

And thanks for your question about a few missing words at the bottom of page 1. Yes two lines dropped off. They are: "detailed water balance for the SFPUC delivery system as a whole. It should contain, as a minimum, how much the diversion goal is from the". Bob H

Greetings,

Thank you for your comments. In reviewing the comments, it appears as though a few words or sentence may be missing in the transition from page one to page 2. Can you let me know? I combined the files into one Adobe Acrobat file (attached) in an effort to help you answer the question.

(See attached file: Restore Hetch Hetchy_072809.pdf)

Regards,
Diana

Mitigation Action #8: Replace Irrigation Well	NI = Population and Housing, Wind and Shadow, Public Services LS = Transportation and Circulation, Greenhouse Gas Emissions, Recreation, Agriculture and Forest Resources, Geology and Soils, Mineral and Energy Resources LSM = Land Use, Aesthetics, Cultural and Paleontological Resources, Air Quality, Utilities and Service Systems, Biological Resources, Hydrology and Water Quality, Hazards and Hazardous Materials SUM = Noise and Vibration																							M-AE-1a: Site Maintenance (Sites 4, 7, 12, 13, 14, 15, and 18 [Alternate]) M-AE-3a: Implement Landscape Screening (Sites 4, 7, and 18 [Alternate]) M-AQ-2a: BAAQMD Basic Construction Measures (All Sites) M-CR-2: Discovery of Archaeological Resources (All Sites except Westlake Pump Station) M-CR-3: Suspend Construction Work if a Paleontological Resource is Identified (All Sites Except Site 9 and Westlake Pump Station) M-CR-4: Accidental Discovery of Human Remains (All Sites Except Westlake Pump Station) M-TR-1: Traffic Control Plan (Sites 2, 4, 5, 6, 7, 10, 12, 13, 14, 15, 17 [Alternate], 18 [Alternate], and 19 [Alternate]) M-NO-1: Noise Control Plan (1, 3, 4, 5, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17 [Alternate], 18 [Alternate], and 19 [Alternate]) M-NO-2: Reduce Vibration Levels during Construction of Pipelines (Sites 3, 4, 12, 15, and 18 [Alternate]) M-UT-1a: Confirm Utility Line Information (All Sites) M-UT-1b: Safeguard Employees from Potential Accidents Related to Underground Utilities (All Sites) M-UT-1c: Notify Local Fire Departments (All Sites) M-UT-1d: Emergency Response Plan (All Sites) M-UT-1e: Advance Notification (All Sites) M-UT-1f: Protection of Other Utilities during Construction (All Sites) M-UT-1g: Ensure Prompt Reconnection of Utilities (All Sites) M-UT-1h: Avoidance of Utilities Constructed or Modified by Other SFPUC Projects (All Sites) M-UT-1i: Coordinate Final Construction Plans with Affected Utilities (All Sites) M-UT-4: Waste Management Plan (All Sites) M-BR-1a: Protection Measures during Construction for Special-status Birds and Migratory Passerines and Raptors (All Sites) M-BR-1b: Protection Measures for Special-status Bats during Tree Removal or Trimming (Sites 1, 3, 4, 7, 10, 11, 12, 15, and 16) M-BR-4a: Identify Protected Trees (Sites 3, 4, 7, 10, 11, 12, 13, 14, 15, and 17 [Alternate]) M-BR-4b: Protected Tree Replacement (Sites 4, 7, 9, 12, 15, and 18 [Alternate]) M-HY-1: Develop and Implement a Stormwater Pollution Prevention Plan (SWPPP) or an Erosion and Sediment Control Plan (All Sites) M-HZ-2a: Preconstruction Hazardous Materials Assessment (All Sites) M-HZ 2b: Health and Safety Plan (All Sites) M-HZ-2c: Hazardous Materials Management Plan (All Sites)

Appendix C
Summary of Impacts and Mitigation Measures for the Groundwater Storage and Recovery Project

Impact Statement	Site 1	Site 2	Site 3	Site 4	WLPS	Site 5 (On-site)	Site 5 (Consol)	Site 6 (On-site)	Site 6 (Consol)	Site 7 (On-site)	Site 7 (Consol)	Site 8	Site 9	Site 10	Site 11	Site 12	Site 13	Site 14	Site 15	Site 16	Site 17 (A)	Site 18 (A)	Site 19 (A)	Mitigation
M-HY-6. Mitigation Action #9: Replace Irrigation Water Source	NI = Population and Housing, Cultural and Paleontological Resources, Wind and Shadow, Utilities and Service Systems, Public Services, Biological Resources, Geology and Soils, Hydrology and Water Quality, Hazards and Hazardous Materials, Mineral and Energy Resources, Agriculture and Forest Resources LS = Land Use, Transportation and Circulation, Noise and Vibration, Greenhouse Gas Emissions, Recreation LSM = Aesthetics, Air Quality																							M-AE-1a: Site Maintenance (Sites 4, 7, 12, 13, 14, 15, and 18 [Alternate]) M-AQ-2a: BAAQMD Basic Construction Measures (All Sites)
Impacts of M-HY-9b: Lake Level Management for Lake Merced	LS = Well Interference, Subsidence, Seawater Intrusion, Adverse Effects on Beneficial Uses of Lake Merced, Water Quality Standards, Groundwater Depletion																							None required
Impact HY-7. Project operations would not result in substantial land subsidence due to decreased groundwater levels in the Westside Groundwater Basin where the historical low water levels are exceeded.	LS																							None required
Impact HY-8. Project operations could result in seawater intrusion due to decreased groundwater levels in the Westside Groundwater Basin.	LS																							None required
Impact HY-9. Project operations could have a substantial, adverse effect on water quality that could affect the beneficial uses of Lake Merced.	LSM																							M-HY-9a: Lake Level Monitoring and Modeling for Lake Merced M-HY-9b: Lake Level Management for Lake Merced
Impact HY-10. Project operation would not have a substantial adverse effect on water quality that could affect the beneficial uses of Pine Lake.	LS																							None required
Impact HY-11. Project operation would not have a substantial adverse effect on water quality that could affect the beneficial uses of Colma Creek, San Bruno Creek, Lomita Channel, or Millbrae Creek.	LS																							None required
Impact HY-12. Project operation would not cause a violation of water quality standards due to mobilization of contaminants in groundwater from changing groundwater levels in the Westside Groundwater Basin.	LS																							None required
Impact HY-13. Project operation would not result in degradation of drinking water quality or groundwater quality relative to constituents for which standards do not exist.	LS																							None required
Impact HY-14. Project operation may have a substantial adverse effect on groundwater depletion in the Westside Groundwater Basin over the very long term.	LSM																							M-HY-14: Prevent Groundwater Depletion
Impact C-HY-1. Project construction could result in a cumulatively considerable contribution to cumulative impacts on surface water hydrology and water quality.	LSM	LSM	LSM	LSM	LSM	LSM	LSM	LSM	LSM	LSM	LSM	LSM	LSM	LSM	LSM	LSM	LSM	LSM	LSM	LSM	LSM	LSM	LSM	M-HY-1: Develop and Implement a Storm Water Pollution Prevention Plan (SWPPP) or an Erosion and Sediment Control Plan (All Sites) M-HY-2: Management of Well Development and Pump Testing Discharges (All Sites except Westlake Pump Station)
Impact C-HY-2. Operation of the proposed Project would result in a cumulatively considerable contribution to cumulative impacts related to well interference.	SUM																							M-HY-6: Ensure Irrigators' Wells Are Not Prevented from Supporting Existing or Planned Land Use Due to Project Operation
Impact C-HY-3. Operation of the proposed Project would not result in a cumulatively considerable contribution to cumulative impacts related to subsidence.	LS																							None required
Impact C-HY-4. Operation of the proposed Project would not have a cumulatively considerable contribution to seawater intrusion.	LS																							None required
Impact C-HY-5. Operation of the proposed Project could have a cumulatively considerable contribution to cumulative impacts on beneficial uses of surface waters.	LSM																							M-HY-9a: Lake Level Monitoring and Modeling for Lake Merced M-HY-9b: Lake Level Management for Lake Merced
Impact C-HY-6. Operation of the proposed Project would not result in a cumulatively considerable contribution to cumulative impacts related to water quality standards	LS																							None required

Appendix D

Mitigation Measure Consistency with the WSIP PEIR

APPENDIX D:
WSIP PEIR WATER SUPPLY IMPACT AND MITIGATION AND CONSISTENCY ANALYSIS

SFPUC REGIONAL GROUNDWATER STORAGE AND RECOVERY PROJECT (CASE NO. 2008.1396E)

The Regional Groundwater Storage and Recovery project (GSR or proposed Project) was analyzed at a program-level in the Water System Improvement Program (WSIP) Program Environmental Impact Report (PEIR)[1] as one of the facility improvement projects under the WSIP. The project details presented in the PEIR were based on the best information available at that time with respect to project design and construction. Details regarding project design, facility layout, construction, staging areas, and other project elements were not available at the time the PEIR was prepared.

The GSR EIR provides a detailed, project-level analysis of the proposed Project based on site-specific and up-to-date information developed subsequent to the preparation of the PEIR. Subsequent to publication of the PEIR, several modifications were made to the GSR Project as more detailed information regarding Project impacts was developed during Project design and site-specific analyses. Although the use of the Westside Groundwater Basin for the GSR Project was identified and analyzed in the PEIR, the location of each proposed well was not specifically identified in the PEIR. Additionally, the analysis of potential impacts of three alternate well sites is included in the project-level EIR to ensure that a total 16 out of 19 possible well sites could be operated, in the case where up to three of the preferred sites were found to be infeasible. However, the Project would only operate a total of 16 wells. Alternate pipeline connections, as well as on-site and consolidated treatment options for three well facilities, are also addressed in the EIR.

Tables D-1a through D-1e summarize the WSIP water supply and system operations impacts and the associated mitigation measures for each geographic region as presented in the PEIR. The reader is referred to the complete WSIP PEIR for a detailed explanation of these summary tables. Note that the categories of significance used in the PEIR are slightly different than those used in this EIR (see table footnotes in Tables D-1a through D-1e).

Table D-2 evaluates the consistency of the project-level impact analysis in the Groundwater Storage and Recovery EIR with the program-level impact analysis previously conducted in the PEIR. Where significance determinations vary between these documents, a brief explanation of the rationale for this determination is provided.

---

[1] San Francisco Planning Department, Final Program Environmental Impact Report for the San Francisco Public Utilities Commission's Water System Improvement Program, File No. 2005-0159E, State Clearinghouse No. 2005092026. Certified October 30, 2008.

Table D-3 lists the programmatic mitigation measures identified in the WSIP PEIR and indicates which of these mitigation measures are applicable to the GSR Project. For the programmatic mitigation measures that are applicable, the table identifies the comparable project-level mitigation measure identified in the GSR Project EIR that either relies on the programmatic measures or identified an equivalent or better site-specific mitigation measure to address the programmatic mitigation measure. The table also provides an explanation for those programmatic mitigation measures that are not applicable to the GSR Project.

TABLE D-1a
Summary of Water Supply Impacts and Mitigation Measures—Tuolumne River System and Downstream Water Bodies

Impact	Significance Determination					Mitigation Measures
	All Impacts (except Biological Resources)	Biological Resource Impacts				
		Sensitive Habitats	Key Special-Status Species	Other Species of Concern	Common Habitats and Species	
STREAM FLOW						
Impact 5.3.1-1: Effects on flow along the Tuolumne River below O'Shaughnessy Dam.	LS					None required.
Impact 5.3.1-2: Effects on flow along Cherry Creek below Cherry Dam.	LS					None required.
Impact 5.3.1-3: Effects on flow along Eleanor Creek below Eleanor Dam.	LS					None required.
Impact 5.3.1-4: Effects on flow along the Tuolumne River below La Grange Dam.	LS					None required.
Impact 5.3.1-5: Effects on flow along the San Joaquin River and the Sacramento–San Joaquin Delta.	LS					None required.
GEOMORPHOLOGY						
Impact 5.3.2-1: Effects on sediment transport and channel characteristics between O'Shaughnessy Dam and Don Pedro Reservoir.	LS					None required.

TABLE D-1a
Summary of Water Supply Impacts and Mitigation Measures—Tuolumne River System and Downstream Water Bodies

Impact	Significance Determination					Mitigation Measures
	All Impacts (except Biological Resources)	Biological Resource Impacts				
		Sensitive Habitats	Key Special-Status Species	Other Species of Concern	Common Habitats and Species	
Impact 5.3.2-2: Effects on sediment transport and channel characteristics below La Grange Dam.	LS					None required.
SURFACE WATER QUALITY						
Impact 5.3.3-1: Effects on water quality in Hetch Hetchy Reservoir and along the Tuolumne River below O'Shaughnessy Dam.	LS					None required.
Impact 5.3.3-2: Effects on water quality in Don Pedro Reservoir and along the Tuolumne River below La Grange Dam.	LS					None required.
Impact 5.3.3-3: Effects on water quality along the San Joaquin River and the Sacramento–San Joaquin Delta.	LS					None required.
SURFACE WATER SUPPLIES						
Impact 5.3.4-1: Effects on Tuolumne River, San Joaquin River, and Stanislaus River water users.	LS					None required.
Impact 5.3.4-2: Effects on Delta water users.	LS					None required.

TABLE D-1a
Summary of Water Supply Impacts and Mitigation Measures—Tuolumne River System and Downstream Water Bodies

Impact	Significance Determination					Mitigation Measures
	All Impacts (except Biological Resources)	Biological Resource Impacts				
		Sensitive Habitats	Key Special-Status Species	Other Species of Concern	Common Habitats and Species	
GROUNDWATER						
Impact 5.3.5-1: Alteration of stream flows along the Tuolumne River, which could affect local groundwater recharge and groundwater levels.	LS					None required.
Impact 5.3.5-2: Alteration of stream flows along the Tuolumne River, which could affect local groundwater quality.	LS					None required.
FISHERIES						
Impact 5.3.6-1: Effects on fishery resources in Hetch Hetchy Reservoir.	LS					None required.
Impact 5.3.6-2: Effects on fishery resources along the Tuolumne River between Hetch Hetchy Reservoir and Don Pedro Reservoir.	LS					None required.
Impact 5.3.6-3: Effects on fishery resources in Don Pedro Reservoir.	LS					None required.

TABLE D-1a
Summary of Water Supply Impacts and Mitigation Measures—Tuolumne River System and Downstream Water Bodies

Impact	Significance Determination					Mitigation Measures
	All Impacts (except Biological Resources)	Biological Resource Impacts				
		Sensitive Habitats	Key Special-Status Species	Other Species of Concern	Common Habitats and Species	
Impact 5.3.6-4: Effects on fishery resources along the Tuolumne River below La Grange Dam.	LS when average annual deliveries from the watersheds are maintained at 265 mgd or less; PSM if deliveries exceed 265 mgd					**Measure 5.3.6-4a, Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water:** The SFPUC will pursue a water transfer arrangement with MID/TID and/or other water agencies which would offset the WSIP's effects on water storage in Don Pedro Reservoir and minimize WSIP-induced changes in releases from La Grange Dam. **If Measure 5.3.6-4a proves to be infeasible, the SFPUC will implement Measure 5.3.6-4b. **Measure 5.3.6-4b, Fishery Habitat Enhancement:** The SFPUC will implement or fund one of two fishery habitat enhancement projects that are consistent with the Lower Tuolumne River Restoration Plan; augmentation of spawning gravel at three selected sites or the filling or isolation from the river of one of the existing inactive quarry pits.
Impact 5.3.6-5: Effects on fishery resources along the San Joaquin River.	LS					None required.

TABLE D-1a
Summary of Water Supply Impacts and Mitigation Measures—Tuolumne River System and Downstream Water Bodies

Impact	Significance Determination					Mitigation Measures
	All Impacts (except Biological Resources)	Biological Resource Impacts				
		Sensitive Habitats	Key Special-Status Species	Other Species of Concern	Common Habitats and Species	
TERRESTRIAL BIOLOGY						
Impact 5.3.7-1: Impacts on riparian habitat and related biological resources in Hetch Hetchy Reservoir and along the bedrock channel portions of the Tuolumne River from O'Shaughnessy Dam to Don Pedro Reservoir.		LS	LS	LS	LS	None required.
Impact 5.3.7-2: Impacts on alluvial features that support meadow and riparian habitat along the Tuolumne River from O'Shaughnessy Dam to Don Pedro Reservoir.		PSM	PSM	PSM	PSM	The SFPUC will implement Measure 5.3.7-2 to reduce adverse impacts on sensitive habitats, key special-status species, other species of concern, and common habitats and species to a less-than-significant level. **Measure 5.3.7-2, Controlled Releases to Recharge Groundwater in Streamside Meadows and Other Alluvial Deposits:** The SFPUC will manage releases to the Tuolumne River from Hetch Hetchy Reservoir during the spring with the goal of recharging groundwater that supports meadow and riparian habitat. The SFPUC will periodically survey meadow habitat to determine the efficacy of release management and will modify releases as necessary to sustain meadow habitat.
Impact 5.3.7-3: Impacts on biological resources in Lake Eleanor and along Eleanor Creek.		LS	LS	LS	LS	None required.

TABLE D-1a
Summary of Water Supply Impacts and Mitigation Measures—Tuolumne River System and Downstream Water Bodies

Impact	Significance Determination					Mitigation Measures
	All Impacts (except Biological Resources)	Biological Resource Impacts				
		Sensitive Habitats	Key Special-Status Species	Other Species of Concern	Common Habitats and Species	
Impact 5.3.7-4: Impacts on biological resources in Lake Lloyd and along Cherry Creek.		LS	LS	LS	LS	None required.
Impact 5.3.7-5: Impacts on biological resources in Don Pedro Reservoir.		LS	LS	LS	LS	None required.
Impact 5.3.7-6: Impacts on biological resources along the Tuolumne River below La Grange Dam.		LS when average annual deliveries from the watersheds are maintained at 265 mgd or less; PSM if deliveries exceed 265 mgd	LS when average annual deliveries from the watersheds are maintained at 265 mgd or less; PSM if deliveries exceed 265 mgd	LS when average annual deliveries from the watersheds are maintained at 265 mgd or less; PSM if deliveries exceed 265 mgd	LS when average annual deliveries from the watersheds are maintained at 265 mgd or less; PSM if deliveries exceed 265 mgd	The SFPUC will implement Measures 5.3.6-4a or 5.3.7-6 to reduce adverse impacts on sensitive habitats, key special-status species, other species of concern, and common habitats and species to a less-than-significant level. **Measure 5.3.6-4a, Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water** – see description above. **If Measure 5.3.6-4a proves to be infeasible, the SFPUC will implement Measure 5.3.7-6. **Measure 5.3.7-6, Lower Tuolumne River Riparian Habitat Enhancement:** Consistent with the Lower Tuolumne River Restoration Plan, the SFPUC will protect and enhance one mile of riparian vegetation within the contemporary floodplain.
Impact 5.3.7-7: Conflicts with the provisions of adopted conservation plans or other approved biological resources plans for the Tuolumne Wild and Scenic River.		LS				None required.

TABLE D-1a

Summary of Water Supply Impacts and Mitigation Measures—Tuolumne River System and Downstream Water Bodies

Impact	Significance Determination					Mitigation Measures
	All Impacts (except Biological Resources)	Biological Resource Impacts				
		Sensitive Habitats	Key Special-Status Species	Other Species of Concern	Common Habitats and Species	
RECREATIONAL AND VISUAL RESOURCES						
Impact 5.3.8-1: Effects on reservoir recreation due to changes in water system operations.	LS					None required.
Impact 5.3.8-2: Effects on river recreation due to changes in water system operations.	LS					None required.
Impact 5.3.8-3: Effects on the aesthetic values of the Tuolumne Wild and Scenic River.	LS					None required.
ENERGY RESOURCES						
Impact 5.3.9-1: Effects on hydropower generation at facilities along the Tuolumne River	B					None required.

NI = No Impact

LS = Less than Significant Impact

PSM = Potentially Significant Impact, Mitigable

SU= Significant Unavoidable Impact

B = Beneficial effect

NA = Not Applicable

TABLE D-1b
Summary of Water Supply Impacts and Mitigation Measures—Alameda Creek Watershed

Impact	Significance Determination					Mitigation Measures
	All Impacts (except Biological Resources)	Biological Resource Impacts				
		Sensitive Habitats	Key Special-Status Species	Other Species of Concern	Common Habitats and Species	
STREAM FLOW						
Impact 5.4.1-1: Effects on flow along Calaveras Creek below Calaveras Reservoir.	LS					None required
Impact 5.4.1-2: Effects on flow along Alameda Creek below the diversion dam.	SU **(Note: subsequent to certification of the WSIP PEIR, this determination was changed to LS[2])**					**Measure 5.4.1-2, Diversion Tunnel Operation:** The SFPUC will implement operational criteria for the diversion dam which will require that water not needed to fill Calaveras Reservoir would be released to Alameda Creek below the diversion dam. **(Note: because Impact 5.4.1-2 was determined to be LS subsequent to certification of the WSIP PEIR, this mitigation measure is no longer required for program implementation.)**
Impact 5.4.1-3: Effects in San Antonio Reservoir and along San Antonio Creek.	LS					None required.

[2] Based on the best available information at that time, the WSIP PEIR made the conservative determination that the WSIP would result in a significant and unavoidable impact related to flow along Alameda Creek below the Alameda Creek Diversion Dam ("Alameda Creek Hydrologic Impact") (see PEIR Chapter 4, Section 5.4.1, Impact 5.4.1-2). Based upon more detailed site-specific data and analysis, the project-level analysis in the Calaveras Dam Replacement Project EIR modified this PEIR impact determination to be less than significant (San Francisco Planning Department 2011).

TABLE D-1b
Summary of Water Supply Impacts and Mitigation Measures—Alameda Creek Watershed

Impact	Significance Determination					Mitigation Measures
	All Impacts (except Biological Resources)	Biological Resource Impacts				
		Sensitive Habitats	Key Special-Status Species	Other Species of Concern	Common Habitats and Species	
Impact 5.4.1-4: Effects on flow along Alameda Creek below the confluence of San Antonio Creek.	LS					None required.
GEOMORPHOLOGY						
Impact 5.4.2-1: Effects on channel formation and sediment transport along Calaveras Creek.	LS					None required.
Impact 5.4.2-2: Effects on channel formation and sediment transport along Alameda Creek downstream of the diversion dam and downstream of the San Antonio Creek confluence.	LS					None required.
Impact 5.4.2-3: Effects on channel formation and sediment transport along San Antonio Creek downstream of San Antonio Reservoir.	LS					None required.
SURFACE WATER QUALITY						
Impact 5.4.3-1: Effects on water quality in Calaveras Reservoir.	LS					None required.
Impact 5.4.3-2: Effects on water quality in San Antonio Reservoir.	LS					None required.
Impact 5.4.3-3: Changes in water quality along Calaveras, San Antonio, and Alameda Creeks.	LS					None required.

TABLE D-1b

		Sensitive Habitats	Key Special-Status Species	Other Species of Concern	Common Habitats and Species	
STREAM FLOW						
Impact 5.5.1-1: Effects on flow along San Mateo Creek.	LS					None required.
Impact 5.5.1-2: Effects on flow along Pilarcitos Creek.	LS					None required.
GEOMORPHOLOGY						
Impact 5.5.2-1: Changes in sediment transport and channel morphology in the Peninsula watershed.	LS					None required.
WATER QUALITY						
Impact 5.5.3-1: Effects on water quality in Crystal Springs Reservoir, San Andreas Reservoir, and San Mateo Creek.	LS					None required.
Impact 5.5.3-2: Effects on water quality in Pilarcitos Reservoir and along Pilarcitos Creek.	PSM					**Measure 5.5.3-2a, Low-head Pumping Station at Pilarcitos Reservoir:** The SFPUC will install a permanent low-head pumping station at Pilarcitos Reservoir which would enable the SFPUC to access and use an additional 350 acre-feet of water from Pilarcitos Reservoir. In years when the WSIP would cause releases from Pilarcitos Reservoir to Pilarcitos Creek to be reduced to reservoir inflow earlier in the summer than under the existing condition (about 25 percent of years in the

TABLE D-1c
Summary of Water Supply Impacts and Mitigation Measures—Peninsula Watersheds

Impact	Significance Determination: All Impacts (except Biological Resources)	Biological Resource Impacts: Sensitive Habitats	Biological Resource Impacts: Key Special-Status Species	Biological Resource Impacts: Other Species of Concern	Biological Resource Impacts: Common Habitats and Species	Mitigation Measures
						hydrologic record), the SFPUC will use the pumping station to augment flow in Pilarcitos Creek with water from the reservoir. The pumping station will draw water from the cool pool of water below the thermocline during times when the reservoir is stratified. The pumping station outlet will be designed to ensure that water discharged to the creek is adequately aerated. **Measure 5.5.3-2b, Aeration System at Pilarcitos Reservoir:** The SFPUC will install a permanent aeration system at Pilarcitos Reservoir. The SFPUC will operate the aeration system as necessary to avoid anoxic conditions and maintain good water quality conditions at the reservoir.
GROUNDWATER						
Impact 5.5.4-1: Alteration of stream flows along Pilarcitos Creek, which could affect groundwater levels and water quality.	LS					None required.

TABLE D-1c

FISHERIES						
Impact 5.5.5-1: Effects on fishery resources in Crystal Springs Reservoir (Upper and Lower).	PSU **(Note: subsequent to certification of the WSIP PEIR, this determination was changed to LS[3])**					**Measure 5.5.5-1, Create New Spawning Habitat Above Crystal Springs Reservoir:** The SFPUC will survey the extent and quality of fish spawning habitat lost due to inundation and, if feasible, create new spawning habitat at a higher elevation. The specifics of this mitigation measure will be determined as part of project-level CEQA review. **(Note: because Impact 5.5.5-5 was determined to be LS subsequent to certification of the WSIP PEIR, this mitigation measure is no longer required for program implementation).**
Impact 5.5.5-2: Effects on fishery resources in San Andreas Reservoir.	LS					None required.
Impact 5.5.5-3: Effects on fishery resources along San Mateo Creek.	LS					None required.

3 Based on the best available information at that time, the WSIP PEIR made the conservative determination that the WSIP could result in a significant and unavoidable impact on fishery resources in Crystal Springs Reservoir related to inundation of spawning habitat upstream of the reservoir (see PEIR Chapter 5, Section 5.5.5, Impact 5.5.5-1). Project-level review of updated, site-specific information that was developed following certification of the PEIR was incorporated into the project-level EIR for the Lower Crystal Springs Dam Improvements Project, and the project-level analysis determined that impacts on fishery resources due to inundation effects would be less than significant (San Francisco Planning Department 2010).

Summary of Water Supply Impacts and Mitigation Measures—Westside Groundwater Basin

Impact	Significance Determination		Mitigation Measures
	North Westside Groundwater Basin	South Westside Groundwater Basin	
RECREATIONAL AND VISUAL RESOURCES			
Impact 5.6-1: Basin overdraft due to pumping from the Westside Groundwater Basin.	PSM	LS	The SFPUC will implement Measure 5.6.1 to reduce adverse impacts on the North Westside Groundwater Basin to a less-than-significant level. **Measure 5.6-1, Groundwater Monitoring to Determine Basin Safe Yield:** The SFPUC will continue ongoing groundwater and lake level monitoring programs to determine the safe yield of the North Westside Groundwater Basin in order to avoid overdraft and associated effects including adverse effects on surface water features and seawater intrusion.
Impact 5.6-2: Changes in water levels in Lake Merced and other surface water features, including Pine Lake, due to decreased groundwater levels in the Westside Groundwater Basin.	PSM	NA	The SFPUC will implement Measures 5.6.1 and 5.6-2 to reduce adverse impacts on the North Westside Groundwater Basin to a less-than-significant level. **Measure 5.6-1, Groundwater Monitoring to Determine Basin Safe Yield** – see description above. **Measure 5.6-2, Implementation of a Lake Level Management Plan:** The SFPUC will develop and implement a lake level management plan identifying strategies for altering pumping patterns or lake augmentation to maintain Lake Merced water levels within the desired long-term range.
Impact 5.6-3: Seawater intrusion due to decreased groundwater levels in the Westside Groundwater Basin.	PSM	LS	The SFPUC will implement Measure 5.6.1 to reduce adverse impacts on the North Westside Groundwater Basin to a less-than-significant level. **Measure 5.6-1, Groundwater Monitoring to Determine Basin Safe Yield** – see description above.
Impact 5.6-4: Land subsidence due to decreased groundwater levels in the Westside Groundwater Basin if the historical low water levels are exceeded.	LS	LS	None required.
Impact 5.6-5: Contamination of drinking water due to groundwater pumping in the Westside Groundwater Basin.	PSM	PSM	The SFPUC will implement Measure 5.6.5 to reduce adverse impacts on the North Westside and South Westside Groundwater Basins to a less-than-significant level. **Measure 5.6.5, Drinking Water Source Assessments for Groundwater Wells:** The SFPUC will develop and implement a source water protection program for wells constructed under the Local and Regional Groundwater Projects that are considered vulnerable to contamination on the basis of the drinking water source assessment prepared in accordance with Department of Public Health Services regulations.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Land Use				
Impact 4.3-1: Temporary disruption or displacement of existing land uses during construction.	PSM	SUM	N	See Impact LU-1: Project construction would have a substantial impact on the existing character of the vicinity and could substantially disrupt or displace existing land uses or land use activities. The PEIR assumed that the 24-hour construction activities would be required for well facility construction and assumed that a new well would be constructed at the Francis Scott Key Elementary School. The analysis assumed that construction activities could disrupt sensitive land uses such as schools and nearby residential uses but implementation of SFPUC Construction Measures #1, #3, #5, #6, #10 and mitigation measures identified in PEIR Chapter 6, would reduce the impact to less than significant. The project-level analysis determined that nighttime construction associated with well drilling would, at some sites, cause temporary construction-noise impacts which feasible mitigation measures cannot reduce to less-than-significant levels. Therefore, the project-level impact would be significant and unavoidable.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.3-2: Permanent displacement or long-term disruption of existing land uses.	PSU	LSM	N	See Impact LU-2: Project operations would result in substantial long-term or permanent impacts on the existing character or disrupt or displace land uses. The PEIR conservatively assumed that the PEIR Regional Groundwater Projects could include sites adjacent to Francis Scott Key School or other sites in San Francisco and northern San Mateo County, which could have resulted in significant and unavoidable impacts on these sensitive land uses even with implementation of SFPUC Construction Measures #6 (compliance with local noise ordinances to the extent feasible) and #10 (locating staging areas away from public view and directing nighttime lighting away from residential areas) as well as recommendations of facility siting studies (Measure 4.3-2). The project-level analysis determined that operation of some of the well facilities would generate nighttime noise levels that could be significant at nearby residences. Implementation of Mitigation Measure M-NO-5 (Operational Noise Control Measures) would reduce noise levels to less-than-significant levels.
Impact 4.17-1: Cumulative disruption of established communities, changes in existing land use patterns, and impacts on the existing visual character.	LS	Land Use - SUM	N	See Impact C-LU-1: Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to land use. The PEIR determined that cumulative development in the vicinity of WSIP projects could disrupt established communities and significantly alter existing land use patterns. However, implementation of SFPUC construction measures and PEIR Measure 4.3-2 would reduce the WSIP's land use and visual impact to less than significant. The project-level analysis determined that both nighttime and daytime construction noise at some well sites would result in significant disruptions to land use, and that combined with impacts of cumulative projects, cumulative land use impacts would be significant and unavoidable.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
		Visual Character - LSM	N	See Impact C-AE-1: Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to scenic resources and visual character. The PEIR determined that cumulative development in the vicinity of WSIP projects could disrupt established communities and significantly alter existing land use patterns. However, implementation of SFPUC construction measures and PEIR Measure 4.3-2 would reduce the WSIP's land use and visual impact to less than significant. The project-level analysis identified the potential for cumulative impacts to visual character from multiple construction projects in the same geographic area. Implementation of mitigation would reduce the impact such that the GSR Project's contribution to cumulative impacts would not be cumulatively considerable.
Visual				
Impact 4.3-3: Temporary construction impacts on scenic vistas or visual character.	LS	SUM	N	See Impact AE-1: The Project would have a substantial adverse impact on a scenic vista, resource, or on the visual character of a site or its surroundings. The PEIR assumed that temporary effects on visual character would be less than significant with implementation of SFPUC Construction Measure #10 (Project Site). The project-level analysis determined that at one site, removal of trees within the SFPUC right-of-way would have a significant and unavoidable impact on the visual character of the site and to a tree mass specifically identified in a local General Plan.
Impact 4.3-4: Permanent adverse impacts on scenic vistas or visual character.	PSM	LSM	Y	See Impact AE-3: The Project would have a substantial adverse impact on a scenic vista, resource, or on the visual character of a site or its surroundings. There is no difference in the impact determination.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.3-5: New permanent sources of light glare.	PSM	LS	Y	See Impact AE-4: The Project would not create a new source of substantial light that would adversely affect day or nighttime views in the area. Also see Impact AE-2: The Project would not create a new source of substantial light that would adversely affect day or nighttime views in the area. The PEIR conservatively assumed that all WSIP projects that include aboveground improvements could include a new source of light or glare and required implementation of design measures (Mitigation Measure 4.3-5) to reduce this impact to a less-than-significant level. Other well facilities would not result in substantial view blockage and therefore would not result in a substantial adverse effect on the site's visual quality. The project-level analysis determined that implementation of the proposed Project would result in additional temporary and permanent lighting; however, new permanent lighting would be in compliance with Title 24 of the California Code of Regulations, would be shielded to direct light downward, and would be controlled by motion sensors with automatic shut-offs. The GSR Project also includes development of a Lighting Plan that would ensure that temporary lighting is focused downward and inward and includes glare control. Therefore, the impact would be less than significant.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Geology, Soils, and Seismicity				
Impact 4.4-1: Slope instability during construction.	PSM	LS	Y	See Impact GE-1: The Project would not be located on a geologic unit or soil that is unstable, or that would become unstable during construction. The WSIP PEIR assumed that the pipelines associated with the PEIR Regional Groundwater Projects could cross areas of potential landslide susceptibility in San Mateo County but implementation of SFPUC Construction Measure #2 Seismic and Geotechnical Studies) as well as a quantified landslide analysis (Measure 4.4-1) would reduce this impact to a less-than-significant level. The project-level analysis included several site-specific geotechnical investigations to assess slope stability hazards. The potential for slopes at the sites to become destabilized during construction was determined to be less than significant, due to the mapped and documented presence of generally dense granular materials, the absence of shallow groundwater, and the presence of vegetation that provides additional strengthening of the near surface soils.
Impact 4.4-2: Erosion during construction.	LS	LSM	N	See Impact HY-1: Project construction activities would degrade water quality as a result of erosion or siltation caused by earthmoving activities or by the accidental release of hazardous construction chemicals during construction. The WSIP PEIR noted that all construction sites would be subject to soil loss and erosion and that implementation of the SFPUC Construction Measure #3 (on-site air and water quality measures) would result in less than significant impacts for all WSIP projects. The project-level EIR does not assume implementation of SFPUC Construction Measure #3. Elements of the SFPUC Standard Construction Measure #3 are included in Mitigation Measure M-HY-1 (Develop and Implement and Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan), which would reduce the GSR Project impact to a less-than-significant level.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.4-3: Substantial alteration of topography.	LS	LS	Y	See Impact GE-2: The Project would not substantially change the topography or any unique geologic or physical features of the site(s). There is no difference in the impact determination.
Impact 4.4-4: Squeezing ground and subsidence during tunneling.	N/A	N/A	Y	Tunneling is not included in the GSR Project. Thus, the significance criterion related to subsidence during tunneling is not applicable.
Impact 4.4-5: Surface fault rupture.	LS	LS	Y	See Impact GE-3: The Project would expose people or structures to substantial adverse effects related to the risk of property loss, injury, or death due to fault rupture, seismic groundshaking, or landslides. The well facility sites, including pipelines, would not be located within the San Andreas Fault Zone and no other active or potentially active faults are known to cross the sites. There is no difference in the impact determination.
Impact 4.4-6: Seismically induced groundshaking.	LS	LSM	N	See Impact GE-3: The Project would expose people or structures to substantial adverse effects related to the risk of property loss, injury, or death due to fault rupture, seismic groundshaking, or landslides. The WSIP PEIR evaluated the potential impacts of seismically induced groundshaking on WSIP facilities and concluded that all potential facilities would experience strong groundshaking from a seismic event, but that the impact would be less than significant. The project-level analysis included the implementation of several site-specific geotechnical investigations to assess groundshaking hazards. Assuming compliance with all applicable building codes and standards, and the recommendations of the site-specific geotechnical investigations as required in Mitigation Measure M-GE-3 (Conduct Site-Specific Geotechnical Investigations and Implement Recommendations), groundshaking risks to GSR facilities and operations would be reduced to a less-than-significant level.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.4-7: Seismically induced ground failure, including liquefaction and settlement.	LS	LSM	N	See Impact GE-4: The Project would be located on a geologic unit or soil that is unstable, or that would become unstable. The WSIP PEIR evaluated the potential impacts of seismically induced ground failure and concluded that all potential facilities would be designed in accordance with the General Seismic Design Requirements and that impacts related to liquefaction and other seismically induced ground failures would be less than significant. The project-level analysis determined that the underlying soil at some of the sites have a moderately high hazard from settlement. Implementation of Mitigation Measure M-GE-3 (Conduct Site-Specific Geotechnical Investigations and Implement Recommendations) which incorporates site-specific geotechnical recommendations to reduce the GSR Project impact to a less-than-significant level.
Impact 4.4-8: Seismically induced landslides or other slope failures.	LS	LS	Y	See Impact GE-3: The Project would expose people or structures to substantial adverse effects related to the risk of property loss, injury, or death due to fault rupture, seismic groundshaking, or landslides. The project-level analysis determined that the potential for seismically induced landslides or slope failures would be less than significant for all sites. There is no difference in the impact determination.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.4-9: Expansive or corrosive soils.	PSM	LS	N	See Impact GE-5: The Project would not be located on corrosive or expansive soil, creating substantial risks to life or property. Based on regional mapping reviewed for the WSIP PEIR, expansive and corrosive soils are mapped in the GSR Project area, and impacts related to these soils were considered potentially significant. The project-level analysis determined that site specific soils are not considered expansive, and that cathodic protection measures that have been incorporated into the design of the GSR Project would ensure that potential impacts related to corrosive soils are less than significant.
Impact 4.17-2: Cumulative exposure of people or structures to geologic and seismic hazards.	LS	LS	Y	See Impact C-GE-1: Construction and operation of the proposed Project could result in significant impacts related to soils and geology. There is no difference in the impact determination.

WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Hydrology and Water Quality				
Impact 4.5-1: Degradation of water bodies as a result of erosion and sedimentation or a hazardous materials release during construction.	LS	LSM	N	See Impact HY-1: Project construction activities would degrade water quality as a result of erosion or siltation caused by earthmoving activities or by the accidental release of hazardous construction chemicals during construction. Although final locations of the well facilities were not determined at the time of publication of the WSIP PEIR, the PEIR indicated that implementation of SFPUC Construction Measure #3 (onsite air and water quality measures during construction), and implementation of control measures in compliance with NPDES permit requirements for projects disturbing more than one acre, would ensure that this impact is less than significant. The project-level EIR does not assume implementation of SFPUC Construction Measures. Implementation of Mitigation Measure M-HY-1 (Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan) is included and would reduce the Project impact to a less-than-significant level.
Impact 4.5-2: Depletion of groundwater resources.	N/A	N/A	Y	The PEIR and project-level EIR determined that construction dewatering would not be required such that depletion of groundwater resources would occur. See PEIR Impacts 5.6-1 through 5.6-6 below for analysis of operational impacts on groundwater resources.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.5-3a: Degradation of water quality due to construction dewatering discharges.	N/A	LSM	N	See Impact HY-1: Project construction activities would degrade water quality as a result of erosion or siltation caused by earthmoving activities or by the accidental release of hazardous construction chemicals during construction. The PEIR assumed that the PEIR Regional Groundwater Projects would not involve dewatering. The project-level analysis determined that the discharge of sediment-laden groundwater to the storm drain system during excavation dewatering could degrade water quality and violate water quality standards, however, implementation of Mitigation Measure M-HY-1 (Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan) would reduce the impact to a less-than-significant level.
Impact 4.5-3b: Degradation of water quality due to construction-related discharges of treated water.	N/A	LSM	N	See Impact HY-2: Discharge of groundwater could result in minor localized flooding, violate water quality standards, and/or otherwise degrade water quality. The PEIR assumed that the PEIR Regional Groundwater Projects would not involve construction-related discharges of water; therefore this impact was determined to not be applicable. The project-level analysis determined that the discharge of sediment-laden groundwater to the storm drain system during well development and pumping tests could degrade water quality and violate water quality standards. Implementation of Mitigation Measure M-HY-2 (Management of Well Development and Pump Testing Discharges) would reduce GSR Project impacts to less-than-significant levels.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.5-4: Flooding and water quality impacts associated with impeding or redirecting flood flows.	PSM	LS	N	See Impact HY-4: Project operations would not impede or redirect flood flows. At the time the PEIR was prepared, the project design conservatively assumed that some Groundwater Project components could be constructed in San Mateo County and could be constructed in a flood zone. Thus, the PEIR determined that impacts related to flooding would be potentially significant but implementation of flood flow protection measures (Measure 4.5-4a), which would be prepared for the project, would reduce impacts to a less-than-significant level. The project-level analysis determined that only one of the proposed project sites is located within a special flood hazard zone. Given that the chemical treatment building at the site would be elevated above the 100-year flood elevation, and because the presence of an at-grade parking area would have a negligible effect on impeding or redirecting flood flows, this impact would be less than significant.
Impact 4.5-5: Degradation of water quality and increased flows due to discharges to surface water during operation.	PSM	LS	N	See Impact HY-5: Project operations would not result in a violation of water quality standards or in the degradation of water quality from the discharge of groundwater during well maintenance. The PEIR analysis determined that the use of treated stormwater for groundwater recharge could affect groundwater quality if the bacterial standards for the source water were less stringent than those for drinking water, a potentially significant impact. Implementation of Measure 4.5-5, which requires treatment to remove nutrients from stormwater and implementation of groundwater monitoring in the vicinity of Lake Merced, would reduce this impact to less than significant. The project-level analysis determined that discharge water would be sent to either the sanitary sewer or the storm drain system; therefore, the discharge water associated with operations of the GSR Project would not violate water quality standards or degrade water quality and any such potential impacts on surface water would be less than significant.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.5-6: Degradation of water quality as a result of alteration of drainage patterns or an increase in impervious surfaces.	LS	LS	Y	See Impact HY-3: Project operation would not alter drainage patterns in such a manner that could result in degraded water quality or cause on- or off-site flooding. Also see Impact HY-5: Project operations would not result in a violation of water quality standards or in the degradation of water quality from the discharge of groundwater during well maintenance. There is no difference in the impact determination.
Impact 4.17-3: Cumulative impacts related to the degradation of water quality, alteration of drainage patterns, increased surface runoff, and flooding hazards.	LS	LSM	N	See Impact C-HY-1: Project construction could result in a cumulatively considerable contribution to cumulative impacts on surface water hydrology and water quality. The PEIR determined that the WSIP projects in conjunction with other projects would not result in cumulative water quality and hydrology effects related to increased erosion and sedimentation, construction-related discharges of treated water or groundwater produced during dewatering, or operational discharges of treated water with implementation of proper BMPs for temporary and permanent erosion control The project-level analysis identified the potential for cumulative impacts to hydrology and water quality from multiple construction projects in the same geographic area. With implementation of Mitigation Measure M-HY-1 (Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan) and Mitigation Measure M-HY-2 (Management of Well Development and Pump Testing Discharge) and compliance with the Waste Discharge Requirements for the SFPUC Drinking Water Transmission System, the GSR Project's contribution to any such cumulative water quality impacts would not be cumulatively considerable.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 5.6-1: Basin overdraft due to pumping from the Westside Groundwater Basin.	LS	SUM	N	See Impact HY-14: Project operation may have a substantial adverse effect on groundwater depletion in the Westside Groundwater Basin over the very long term. Also, see Impact HY-6: Project operation would decrease the production rate of existing nearby irrigation wells due to localized groundwater drawdown within the Westside Groundwater Basin such that existing or planned land use(s) may not be fully supported. The PEIR determined that impacts related to basin overdraft and associated adverse conditions in the South Westside Groundwater Basin would be less than significant, given that the overall conjunctive-use program would be designed to take advantage of vacated aquifer storage that has become available as a result of historical groundwater pumping in the basin. The project-level analysis also determined that the GSR Project may cause an incremental depletion of groundwater storage over the long-term, which is conservatively deemed a significant impact because over the very long-term this could result in a substantial regional deficit in aquifer storage that would may not fully support existing or planned land uses. Implementation of Mitigation Measure M-HY-14 (Prevent Groundwater Depletion) would reduce impacts of the Project on long-term depletion of groundwater storage to less-than-significant levels.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 5.6-2: Changes in water levels in Lake Merced and other surface water features, including Pine Lake, due to decreased groundwater levels in the Westside Groundwater Basin.	N/A	LSM	N	See Impact HY-9: Project operation could have a substantial, adverse effect on water quality that could affect the beneficial uses of Lake Merced. Also see Impact HY-10: Project operation would not have a substantial adverse effect on water quality that could affect the beneficial uses of Pine Lake, and Impact HY-11: Project operation would not have a substantial adverse effect on water quality that could affect the beneficial uses of Colma Creek, San Bruno Creek, Lomita Channel, or Millbrae Creek. The PEIR determined that there are no major surface water features in the South Westside Groundwater Basin that would be affected. The project-level analysis determined that significant impacts could occur to Lake Merced, and Mitigation Measures M-HY-9a (Lake Level Monitoring and Modeling for Lake Merced) and M-HY-9b (Lake Level Management for Lake Merced) is provided to reduce impacts to a less-than-significant level. The project-level analysis determined that the impact on the beneficial uses of Pine Lake and other surface water bodies would be less than significant.
Impact 5.6-3: Seawater intrusion due to decreased groundwater levels in the Westside Groundwater Basin.	LS	LS	Y	See Impact HY-8: Project operation would not result in seawater intrusion due to decreased groundwater levels in the Westside Groundwater Basin. The PEIR determined that impacts related to the potential to cause seawater intrusion the South Westside Groundwater Basin would be less than significant. The project-level analysis determined that the GSR Project would not cause lower average groundwater levels that would induce seawater intrusion in either the North or South Westside Groundwater Basin.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 5.6-4: Land subsidence due to decreased groundwater levels in the Westside Groundwater Basin if the historical low water levels are exceeded.	LS	LS	Y	See Impact HY-7: Project operation would not result in substantial land subsidence due to decreased groundwater levels in the Westside Groundwater Basin where the historical low water levels are exceeded. The PEIR determined that the potential for land subsidence would be less than significant, given the formations comprising the aquifers of the North Westside Groundwater Basin, and because groundwater levels associated with the PEIR Regional Groundwater Projects would likely be higher than historical flows in the South Westside Groundwater Basin. The project-level analysis estimated subsidence due to GSR Project operations at three representative locations. The estimated subsidence was less than the significance thresholds established for the analysis, therefore, subsidence due to Project operation was determined to be less than significant.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 5.6-5: Contamination of drinking water due to groundwater pumping in the Westside Groundwater Basin.	PSM	LS	N	See Impact HY-12: Project operation would not cause a violation of water quality standards due to mobilization of contaminants in the groundwater from changing groundwater levels in the Westside Groundwater Basin. The PEIR noted that until production well locations were selected and a drinking water source assessment performed, the potential for contamination of a drinking water well could not be fully evaluated. Therefore, the PEIR considered impacts related to potential contamination of a drinking water source as potentially significant, which would be reduced to a less-than-significant level with implementation of Measure 5.6-5, Drinking Water Source Assessments for Groundwater Wells. The project-level analysis included preliminary Drinking Water Assessment and Protection Program reports used to characterize the vulnerability of proposed wells sites to possible contaminating activities. The analysis determined that potential GSR Project impacts on groundwater from possible contaminating activities would be less than significant, given that wells would be protected against contamination by the construction of an annular seal composed of sand/cement grout, water would be blended or treated to ensure all drinking water standards are met. The analysis also determined that the potential impact from mobilization or spreading of contaminants in groundwater as a result of increased pumping would be less than significant.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 5.6-6: Drinking water contaminants above maximum contaminant levels and adverse effects of adding treated groundwater to the distribution system.	LS	LS	N	See Impact HY-12: Project operation would not cause a violation of water quality standards due to mobilization of contaminants in groundwater from changing groundwater levels in the Westside Groundwater Basin. Also see Impact HY-13: Project operation would not result in degradation of drinking water quality or groundwater quality relative to constituents for which standards do not exist. The PEIR determined the groundwater developed for potable uses under the WSIP would be treated or blended with system water to meet all primary and secondary drinking water standards. Therefore, programmatic impacts related to exceedances in drinking water standards would be less than significant. The project-level analysis determined that potential GSR Project impacts on drinking water quality from regulated and non-regulated constituents would be less than significant. As described in GSR Chapter 3, Project Description, Section 3.4.2.2 (Well Facility Types), any violation of drinking water standards at production wells resulting from Project operation would be addressed by proposed treatment and/or blending.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 5.7.5-1: Cumulative impacts on the North Westside Groundwater Basin.	LS	LSM	N	See Impacts C-HY-2, C-HY-3, C-HY-4, C-HY-5, and C-HY-8. The PEIR did not evaluate cumulative impacts of the GSR Project in the North Westside Groundwater Basin The project-level analysis concludes that implementation of Mitigation Measures M-HY-9a (Lake Level Monitoring and Modeling for Lake Merced) and M-HY-9b (Lake Level Management for Lake Merced) would reduce the GSR Project's impact in the North Westside Groundwater Basin at Lake Merced on long-term lake-level declines to a less-than-cumulatively considerable level. The project-level analysis determined that the GSR Project would not have a considerable contribution to the cumulative impact relative to seawater intrusion in the North Westside Groundwater Basin, and the estimated subsidence due to operation of the cumulative conditions scenario in the North Westside Groundwater Basin was also determined to be less than significant. Implementation of Mitigation Measure M-HY-14 (Prevent Groundwater Depletion), which addresses impacts in both the North and South Westside Groundwater Basins would reduce the Project's impact on long-term depletion of groundwater storage to less-than-cumulatively considerable levels.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 5.7.5-2: Cumulative impacts on the South Westside Groundwater Basin.	LS	SUM	N	See Impacts C-HY-2, C-HY-3, C-HY-4, C-HY-5, C-HY-6, C-HY-7, and C-HY-8. The PEIR determined that implementation of the proposed conjunctive-use program should result in higher average groundwater levels in the northern portion of the South Westside Groundwater Basin as a result of the coordinated use of surface water and groundwater. The PEIR determined that implementation of the operating agreement(s) would ensure that impacts related to basin overdraft, saltwater intrusion, and land subsidence would be less than significant, and that because there are no other planned future uses of groundwater in this portion of the basin, cumulative groundwater impacts would be less than significant. The project-level analysis determined implementation of Mitigation Measure M-HY-6 (Ensure Existing Irrigator's Wells Are Not Prevented from Supporting Existing or Planned Land Use Due to Project Operation) would reduce the GSR Project's contribution to cumulative impacts on well interference. However, because the feasibility of the mitigation measure cannot be assured until the existing irrigation well owners have agreed to allow mitigation to take place on their property, the Project's impact is conservatively deemed to be cumulatively considerable. Implementation of Mitigation Measure M-HY-14 (Prevent Groundwater Depletion) would reduce the Project's impact on long-term depletion of groundwater storage to less-than-cumulatively considerable levels in the South Westside Groundwater Basin. The Project-level analysis determined that the Project would not have a considerable contribution to the cumulative impact relative to seawater intrusion or subsidence in the South Westside Groundwater Basin.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Biological Resources				
Impact 4.6-1: Impacts on wetlands and aquatic resources.	PSM	LSM	Y	See Impact BR-3: The Project would impact jurisdictional wetlands or waters of the United States. There is no difference in the impact determination.
Impact 4.6-2: Impacts on sensitive habitats, common habitats, and heritage trees.	PSM	LSM	Y	See Impact BR-2: Project construction would adversely affect riparian habitat or other sensitive natural communities. Also see Impact BR-4: Project construction would conflict with local tree preservation ordinances. There is no difference in the impact determination.
Impact 4.6-3: Impacts on key special-status species – direct mortality and/or habitat effects.	LS	LSM	N	See Impact BR-1: Project construction would adversely affect candidate, sensitive, or special-status species. Also see Impact BR-5: Project operation would adversely affect candidate, sensitive, or special-status species. The PEIR analysis assumed that the PEIR Regional Groundwater Project facilities would be located in previously disturbed areas that do not support key special-status species; therefore, the impact in the PEIR was determined to be less than significant. The project-level analysis determined that vegetation removal and operational noise of the GSR Project at some sites could result in significant impacts to special-status birds, migratory passerines and raptors, special status bats, and monarch butterflies. Implementation of Mitigation Measures M-BR-1a, -1b, -1c, -1d and Mitigation Measure M-NO-5 would reduce impacts to a less-than-significant level.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.6-4: Water discharge effects on riparian and/or aquatic resources.	N/A	LSM	N	See Impact BR-3: The Project would impact jurisdictional wetlands or waters of the United States. The PEIR assumed that the Groundwater Projects would not involve dewatering. The Project-level analysis determined that construction at some sites could result in impacts due potential uncontrolled runoff and sedimentation to jurisdictional wetlands and waters. Implementation of Mitigation Measure M-HY-1 (Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan) would reduce the Project impact a less-than-significant level.
Impact 4.6-5: Conflicts with adopted conservation plans or other approved biological resources plans.	N/A	NI	Y	See GSR Section 5.14.3.2 (Approach to Analysis), under the heading "Areas of No Project Impact." The PEIR noted that there are no adopted plans in the area proposed for the PEIR Regional Groundwater Projects. The project-level analysis also determined that no such plans have been adopted in the areas that would be affected by the GSR Project.
Impact 4.17-4: Cumulative loss of sensitive biological resources.	LS	LSM	N	See Impact C-BR-1: Construction and operation of the proposed Project could result in significant cumulative impacts related to biological resources. The PEIR determined that cumulative impacts on biological resources would be less than significant through implementation of PEIR Measures 4.6-1 through 4.6-3 as well as Measure 4.16-4a. The project-level analysis identified the potential under the GSR Project for cumulative impacts to biological resources from multiple construction projects in the same geographic area. Implementation of mitigation measures would reduce the impact such that the GSR Project's contribution to cumulative impacts would not be cumulatively considerable.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
	N/A	LSM	N	Impacts BR-6 through BR-9 and C-BR-2 evaluate potential Project impacts on biological resources at Lake Merced. The PEIR did not evaluate the potential for adverse effects on biological resources at Lake Merced related to project operation. The project-level analysis determined that significant impacts could occur under the GSR Project to biological resources at Lake Merced, and mitigation is provided to reduce impacts to a less-than-significant level. Implementation of mitigation would also reduce the impact such that the GSR Project's contribution to cumulative impacts would not be cumulatively considerable.
Cultural Resources				
Impact 4.7-1: Impacts on paleontological resources.	PSM	LSM	Y	See Impact CR-3: Project construction could result in a substantial adverse effect by destroying a unique paleontological resource or site. There is no difference in the impact determination.
Impact 4.7-2: Impacts on archaeological resources.	PSM	LSM	Y	See Impact CR-2: Project construction could cause an adverse change in the significance of an archaeological resource. Also see Impact CR-4: Project construction could result in a substantial adverse effect related to the disturbance of human remains. There is no difference in the impact determination.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.7-3: Impacts on historical significance of a historic district or a contributor to a historic district.	N/A	LSM	N	See Impact CR-1: Project construction could cause an adverse change in the significance of a historical resource. Also see Impact CR-5: Project facilities could cause an adverse change in the significance of a historical resource. The WSIP PEIR concluded that the PEIR Regional Groundwater Projects would add new facilities to the WSIP system or upgrade existing non-historic facilities, and therefore, would not affect historic components of the regional system. The project-level analysis determined that construction and operation of the GSR Project could affect the eligibility of listing the Golden Gate National Cemetery to the National Register. Implementation of mitigation is therefore included to reduce the Project impact to a less-than-significant level.
Impact 4.7-4: Impacts on the historical significance of individual facilities resulting from demolition or alteration.	N/A	LSM	N	See Impact CR-1: Project construction could cause an adverse change in the significance of a historical resource. Also see Impact CR-5: Project facilities could cause an adverse change in the significance of a historical resource. The PEIR assumed that demolition under the PEIR Regional Groundwater Projects would be limited to paved areas and playgrounds at the Francis Scott Key School Annex, and West and South Sunset Playgrounds. The project-level analysis determined that construction and operation of the GSR Project could affect the eligibility of listing the Golden Gate National Cemetery to the National Register. Implementation of mitigation is therefore included to reduce the Project impact to a less-than-significant level.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.7-5: Impacts on adjacent historic architectural resources.	LS	LSM	N	See Impact CR-1: Project construction could cause an adverse change in the significance of a historical resource. Also see Impact CR-5: Project facilities could cause an adverse change in the significance of a historical resource. The WSIP PEIR noted that under the PEIR Regional Groundwater Projects new facilities would be added to existing, non-historic facilities. The project-level analysis determined that construction and operation of the GSR Project could affect the eligibility of listing the Golden Gate National Cemetery to the National Register. Implementation of mitigation is therefore included to reduce the Project impact to a less-than-significant level.
Impact 4.17-5: Cumulative increase in impacts on archaeological, paleontological, and historical resources.	PSU	LSM	N	See Impact C-CR-1: Construction of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts on historical, archaeological, or paleontological resources, or human remains. The PEIR conservatively assumed that, in combination, projects in the Sunol Valley and Peninsula regions could result in significant impacts on individual historical resources or on potential historic districts (if historic districts were determined to be present). The PEIR did not describe cumulative impacts on cultural resources in the San Francisco region. The project-level analysis identified the potential under the GSR Project for cumulative impacts to cultural resources from multiple construction projects in the same geographic area. Implementation of mitigation would reduce the impact such that the GSR Project's contribution to cumulative impacts would not be cumulatively considerable.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Traffic, Transportation, and Circulation				
Impact 4.8-1: Temporary reduction in roadway capacity and increased traffic delays.	PSM	LSM	Y	See Impact TR-1: The Project would conflict with an applicable plan, ordinance or policy establishing measures of effectiveness for the performance of the circulation system. There is no difference in the impact determination.
Impact 4.8-2: Short-term traffic increases on roadways.	LS	LS	Y	See Impact TR-1: The Project would conflict with an applicable plan, ordinance or policy establishing measures of effectiveness for the performance of the circulation system. There is no difference in the impact determination.
Impact 4.8-3: Impaired access to adjacent roadways and land uses.	PSM	LSM	Y	See Impact TR-2: The Project would temporarily impair emergency access to adjacent roadways and land uses during construction. There is no difference in the impact determination.
Impact 4.8-4: Temporary displacement of on-street parking.	PSM	NI	N	Since publication of the PEIR, the significance criterion specifically pertaining to displacement of on-street parking has been deleted from the San Francisco Planning Department's initial study checklist (San Francisco Planning Department 2010). The GSR Project EIR did not identify any secondary impacts associated with loss of parking.
Impact 4.8-5: Increased traffic safety hazards during construction.	PSM	LSM	Y	See Impact TR-1: The Project would conflict with an applicable plan, ordinance or policy establishing measures of effectiveness for the performance of the circulation system. Also see Impact TR-3: The Project would temporarily decrease the performance and safety of public transit, bicycle, and pedestrian facilities during construction. There is no difference in the impact determination.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.8-6: Long-term traffic increases during facility operation.	LS	LS	Y	See Impact TR-4: Project operations and maintenance activities would not conflict with an applicable plan or policies regarding performance of the transportation system or alternative modes of transportation. There is no difference in the impact determination.
Impact 4.17-6: Cumulative traffic increases on local and regional roads.	PSU	LSM	N	See Impact C-TR-1: Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to transportation and circulation. The WSIP PEIR cumulative analysis determined that significant cumulative impacts could occur during concurrent construction of nearby projects, including non-SFPUC projects, and based on the conservative assumption that interagency coordination of construction traffic might not always be possible; this impact was determined to be potentially significant and unavoidable. The project-level analysis identified the potential under the GSR Project for cumulative impacts from multiple construction projects in the same geographic area. Implementation of mitigation would reduce the impact such that the GSR Project's contribution to cumulative impacts would not be cumulatively considerable.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Air Quality				
Impact 4.9-1: Construction emissions of criteria pollutants.	LS	LSM	N	See Impact AQ-2: Emissions generated during construction activities would violate air quality standards and would contribute substantially to an existing air quality violation. The WSIP PEIR identified the requirement for a dust control plan and implementation of dust control measures as part of the SFPUC Construction Measures. The project-level EIR does not assume implementation of SFPUC Construction Measures. The project-level analysis determined that the generation of fugitive dust during construction would result in a significant impact. Implementation of Mitigation Measures M-AQ-2a (BAAQMD Basic Construction Measures) and Mitigation Measure M-AQ-2b (NOx Reduction during Construction of Alternate Sites) would reduce this impact to a less-than-significant level.
Impact 4.9-2: Exposure to diesel particulate matter during construction.	LS	LSM	N	See Impact AQ-3: Project construction would expose sensitive receptors to substantial pollutant concentrations. Also see Impact AQ-6: Project operations would not expose sensitive receptors to substantial pollutant concentrations. The PEIR assumed a determination of less than significant due to the relatively low amount of diesel particulate emissions expected to be generated by haul truck traffic. The project-level analysis determined that under the GSR Project the BAAQMD thresholds utilized as significance thresholds in the EIR would be exceeded for one of the modeling groups evaluated. Implementation of Mitigation Measure M-AQ-3 (Construction Health Risk Mitigation) would reduce this temporary impact to a less-than-significant level. The project-level analysis determined that operational impacts would be less than significant.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.9-3: Exposure to emissions (possibly including asbestos) from tunneling.	PSM	N/A	N	The PEIR analysis was based on a project design that could require tunneling using jack-and-bore construction at roadway crossings. Updated Project design information indicates that tunneling is not included in the GSR Project. Thus, the significance criterion related to exposure to emissions in tunnels is not applicable.
Impact 4.9-4: Air pollutant emissions during project operation.	LS	LS	Y	See Impact AQ-5: Project operations would not violate air quality standards or contribute substantially to an existing air quality violation. There is no difference in the impact determination.
Impact 4.9-5: Odors generated during project operation.	LS	LS	Y	See Impact AQ-7: Project operations would not create objectionable odors affecting a substantial number of people. There is no difference in the impact determination.
Impact 4.9-6: Secondary emissions at power plants.	LS	LS	Y	See Impact ME-2: The Project would not encourage activities that result in the use of large amounts of fuel and energy in a wasteful manner during operation. For all WSIP facility improvement projects, the PEIR analysis assumed any incremental increase in power demand would not result in significant secondary air quality impacts. The project-level analysis is consistent with the PEIR analysis and determined that the GSR Project would not increase energy demands. Thus, this PEIR impact was not specifically called out in the project-level analysis.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.9-7: Conflict with implementation of applicable regional air quality plans addressing criteria air pollutants and state goals for reducing emissions.	LS	LS	Y	See Impact AQ-1: Construction of the Project would not conflict with or obstruct implementation of applicable air quality plans. There is no difference in the impact determination.
Impact 4.17-7: Cumulative increases in construction and/or operational emissions in the region.	PSU	LSM	N	See Impact C-AQ-1: Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to air quality. The PEIR determined that cumulative impacts due to emissions of criteria pollutants would be PSU because the WSIP projects in combination with the cumulative projects would result in regionwide cumulative increases in air emissions during project operations and the residual contribution from each project would contribute to the region's nonattainment status for ozone and particulate matter. Cumulative impacts related to exposure to diesel particulate matter would also be potentially significant and unavoidable because of the lack of certainty about the timing of many of the cumulative projects that might use common haul routes. The project-level analysis identified the potential under the GSR Project for cumulative impacts to NOx emissions if all sites, including alternate sites, were constructed. Implementation of Mitigation Measure M-AQ-2b (NOx Reduction during Construction of Alternate Sites) would reduce NOx emissions to less-than-cumulatively considerable (less than significant) levels by requiring construction contractors to use newer equipment or retrofitted equipment that would create fewer emissions of NOx.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Noise and Vibration				
Impact 4.10-1: Disturbance from temporary construction-related noise increases.	PSU	SUM	Y	See Impact NO-1: Project construction would result in noise levels in excess of local standards. Also see Impact NO-3: Project construction would result in a substantial temporary increase in ambient noise levels. There is no difference in the impact determination.
Impact 4.10-2: Temporary noise disturbance along construction haul routes.	PSU	LS	N	See Impact NO-4: Project construction would not result in a substantial temporary increase in ambient noise levels along construction haul routes. The PEIR assumed that any nighttime truck operations greater than 1 truck per hour could exceed the sleep interference criterion during construction of the PEIR Regional Groundwater Projects. Implementation Mitigation Measures 4.10-2a (limiting hourly truck volumes during the day) and 4.10-2b (restricting of nighttime truck operations) could reduce the impact, but even with implementation of this measure, the PEIR determined that the impact would be potentially significant and unavoidable. The project-level analysis for the GSR Project determined that truck deliveries would not occur at nighttime, and estimated noise levels would fall below the daytime construction threshold. Therefore, the impacts from noise along construction haul routes would be less than significant.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.10-3: Disturbance due to construction-related vibration.	PSU	LSM	N	See Impact NO-2: Project construction would result in excessive groundborne vibration. The PEIR assumed that potentially significant vibration effects could result if there are any sensitive receptors located within 100 feet of proposed facilities but implementation of vibration controls (Measures 4.10-31 and 4.10-3b) would help reduce impacts. The analysis conservatively assumed that construction could occur during nighttime hours; therefore, the impact was considered potentially significant and unavoidable. The project-level analysis determined that construction-related vibration at some GSR sites could result in significant impacts on adjacent structures. Implementation of Mitigation Measure M-NO-2 (Reduce Vibration Levels during Construction of Pipelines) would reduce the Project impact to a less-than-significant level.
Impact 4.10-4: Disturbance due to long-term noise increases.	LS	LSM	N	See Impact NO-5: Operation of the Project would result in exposure of people to noise levels in excess of local noise standards or result in a substantial permanent increase in ambient noise levels in the Project vicinity. The PEIR evaluation of long-term noise increases concluded that noise associated with standby power would be less than significant. The evaluation in the PEIR for other operational noise noted that the project-specific evaluations would define design measures needed to ensure that operational noise levels are maintained at acceptable levels. The project-level analysis determined that under the GSR Project operational noise levels at some sites would exceed established sleep interference thresholds. Implementation of Mitigation Measure M-NO-5 (Operational Noise Control Measures) would reduce the Project impact to a less-than-significant level.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.17-8: Cumulative increases in construction-related and operational noise.	PSU	SUM	Y	See Impact C-NO-1: Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to noise. There is no difference in the impact determination.
Public Services and Utilities				
Impact 4.11-1: Potential temporary damage to or disruption of existing regional or local public utilities.	PSM	LSM	Y	See Impact UT-1: Project construction could result in potential damage to or temporary disruption of existing utilities during construction. There is no difference in the impact determination.
Impact 4.11-2: Temporary adverse effects on solid waste landfill capacity.	PSM	LS	N	See Impact UT-3: Project construction would not result in adverse effects on solid waste landfill capacity. The WSIP PEIR determined that solid waste could impact permitted landfill capacity and noted that potential impacts from individual WSIP projects would be evaluated in more detail in a separate project-level CEQA review. The project-level analysis determined that there is sufficient landfill capacity for GSR Project spoils and the impact would be less than significant with no mitigation required.
Impact 4.11-3: Impacts related to compliance with statutes and regulations related to solid waste.	PSM	LSM	Y	See Impact UT-4: Project construction could result in a substantial adverse effect related to compliance with federal, State, and local statutes and regulations pertaining to solid waste. There is no difference in the impact determination.
Impact 4.11-4: Impacts related to the relocation of utilities.	PSM	LSM	Y	See Impact UT-1: Project construction could result in potential damage to or temporary disruption of existing utilities during construction. There is no difference in the impact determination.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.17-9: Cumulative impacts related to disruption of utility service or relocation of utilities.	LS	LSM	N	See Impact C-UT-1: Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to utilities and service systems. The PEIR determined that construction of the WSIP projects could disrupt utility services or require temporary or permanent relocation of utilities. However, the PEIR determined that these potential impacts would be site-specific rather than additive and would be mitigated on a site-specific basis and, thus, this cumulative impact was considered less than significant. The project-level analysis identified the potential under the GSR Project for cumulative impacts from multiple construction projects in the same geographic region. The analysis determined that implementation of mitigation would reduce the impact such that the GSR Project's contribution to cumulative impacts would not be considerable.
	N/A	LS	N	See Impact UT-2: Project construction would not exceed the capacity of wastewater treatment facilities, exceed wastewater treatment requirements, require or result in the construction of new or expansion of existing wastewater treatment facilities or stormwater drainage facilities, the construction of which could cause significant environmental effects. Also see Impact UT-5: Project operation would not exceed the capacity of wastewater treatment facilities, exceed wastewater treatment requirements, require or result in the construction of new or expansion of existing wastewater treatment facilities or stormwater drainage facilities, the construction of which could cause significant environmental effects. The WSIP PEIR did not evaluate impacts related to the potential exceedance of wastewater treatment facilities, wastewater treatment requirements, or the construction of new wastewater or storm drainage facilities.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Recreational Resources				
Impact 4.12-1: Temporary conflicts with established recreational uses during construction.	PSM	LSM	Y	See Impacts RE-1 through RE-3 for a discussion of temporary conflicts with recreational uses during construction. There is no difference in the impact determination.
Impact 4.12-2: Conflicts with established recreational uses due to facility siting and project operation.	PSM	LS	N	See Impact RE-4: The Project would not damage recreational resources during operation. Also see Impact RE-5: The Project would not deteriorate the quality of the recreational experience during operation. The PEIR analysis assumed that operation of groundwater facilities constructed in City-owned parks and recreational facilities would result in potentially significant impacts on recreational resources but implementation of architectural design, landscaping, and tree removal measures (Measures 4.3-4a, 4.3-4b, 4.3-4c, and 4.3-4d), as well as appropriate siting of proposed facilities (Measure 4.12-2), would reduce potential impacts to a less-than-significant level. The project-level analysis concluded that no significant recreational conflicts would occur from GSR Project operation, and that the Project impact would be less than significant.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.17-10: Cumulative effects on recreational resources during construction.	LS	LS	Y	See Impact C-RE-1: Construction and operation of the proposed Project would not result in significant cumulative impacts on recreational resources. There is no difference in the impact determination.
	N/A	LS	N	Impact RE-6 evaluates potential Project impacts on recreational resources at Lake Merced. The PEIR did not directly evaluate the potential for adverse effects on recreational resources at Lake Merced related to GSR Project operation. The PEIR did evaluate changes in water levels in Lake Merced due to proposed pumping under the Local Groundwater Projects (SF-2), and determined that while direct effects on lake levels are not expected, indirect effects could occur. The PEIR analysis included implementation of Measures 5.6-1 and 5.6-2, and noted that a more detailed analysis of the lake-aquifer relationship would be required as part of project-level CEQA reviews. The project-level analysis determined that the GSR Project would result in minor changes in lake depth and surface area that would have a negligible effect on the scenic quality of the lake and which would not encroach on trails or access areas. In addition, the Project would be consistent with the *Western Shoreline Area Plan* policies for Lake Merced. Therefore, the Project impact on recreational resources was found to be less than significant.
Agricultural Resources				
Impact 4.13-1: Temporary conflicts with established agricultural resources.	N/A	NI	Y	See GSR Section 5.19 (Agriculture and Forest Resources).

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.13-2: Conversion of farmlands to nonagricultural uses.	N/A	NI	Y	See GSR Section 5.19 (Agriculture and Forest Resources).
Hazards				
Impact 4.14-1: Potential to encounter hazardous materials in soil or and groundwater.	PSM	LSM	Y	See Impact HZ-2: The Project would result in a substantial adverse effect related to reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment during construction. There is no difference in the impact determination.
Impact 4.14-2: Exposure to naturally occurring asbestos during construction.	LS	NI	N	See GSR Section 5.17.1.4 (Potential Presence of Naturally Occurring Asbestos). The PEIR found that the PEIR Regional Groundwater Projects would have a low likelihood of encountering asbestos because there is not ultramafic rock units mapped in the area. The project-level analysis determined that under the GSR Project no ultramafic rock units occur in the areas of the proposed facility sites, therefore, naturally occurring asbestos is not likely to be encountered.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.14-3: Risk of fires during construction.	LS	LS	N	See GSR Section 5.17.1.5 (Fire Hazards). Also see Impact HZ-7: The Project would not expose people or structures to a significant risk of loss, injury, or death involving fires At the time the WSIP PEIR was prepared, the locations of specific PEIR Regional Groundwater Project components had not been determined. Therefore, the PEIR conservatively assumed that the projects could be located within high fire hazard zones in San Francisco. As described in GSR Section 5.17.1.5 (Fire Hazards) of the project-level EIR, the facility sites are located on urban land in non-fire hazard severity zones. The project-level analysis also determined that impacts on the exposure of people or structures to fire risk due to changes in Lake Merced water levels would be less than significant.
Impact 4.14-4: Gassy conditions in tunnels.	LS	N/A	N	The PEIR analysis was based on a project design that could require tunneling using jack-and-bore construction at roadway crossings. Updated Project design information indicates that tunneling is not included in the GSR Project. Thus, the significance criterion related to gassy conditions in tunnels is not applicable.
Impact 4.14-5: Exposure to hazardous building materials.	PSM	LSM	Y	See Impact HZ-2: The Project would result in a substantial adverse effect related to reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment during construction. There is no difference in the impact determination.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.14-6: Accidental hazardous materials release from construction equipment.	LS	LSM	N	See Impact HZ-2: The Project would result in a substantial adverse effect related to reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment during construction. The PEIR assumed that impacts related to accidental releases of hazardous materials from construction equipment would be less than significant with implementation of SFPUC Construction Measure #7 (Hazardous Materials). The project-level EIR does not assume implementation of SFPUC Construction Measure #10. The project-level analysis identified potential significant impacts, and includes implementation of mitigation that would reduce the GSR Project impact to a less-than-significant level.
Impact 4.14-7: Increased use of hazardous materials during operation.	LS	LS	Y	See Impact HZ-4: The Project would not create a hazard to the public or environment from the routine transport, use, or disposal of hazardous materials or accidental release of hazardous materials during operation. There is no difference in the impact determination.
Impact 4.14-8: Emission or use of hazardous materials within 1/4 mile of a school.	LS	LSM	N	See Impact HZ-3: The Project would result in impacts from the emission or use of hazardous materials within 0.25 mile of a school during construction. Also see Impact HZ-5: The Project would not result in impacts from the emission or use of hazardous materials within 0.25 mile of a school during operation. The WSIP PEIR assumed that impacts related to accidental release of hazardous materials from construction equipment would be less than significant with implementation of SFPUC Construction Measure #7 (Hazardous Materials). The project-level analysis concluded that under the GSR Project significant impacts could occur during construction at sites on or immediately adjacent to schools, and operational impacts would be less than significant. Implementation of mitigation would reduce the construction-related Project impact to a less-than-significant level.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.17-12: Cumulative effects related to hazardous conditions and exposure to or release of hazardous materials.	LS	LSM	N	See Impact C-HZ-1: Construction and operation of the proposed Project could result in a cumulatively considerable contribution to cumulative impacts related to hazards and hazardous materials. The PEIR determined that due to the site-specific nature of hazardous materials impacts and mitigation measures, there would be no potential for cumulative effects from construction of WSIP projects in conjunction with other cumulative developments. The PEIR determined that compliance with applicable laws and regulations and with implementation of SFPUC construction measures, this cumulative impact would be less than significant. The project-level analysis identified the potential for cumulative impacts from multiple construction projects in the same geographic region. Implementation of mitigation would reduce the impact such that the GSR Project's contribution to cumulative impacts would not be cumulatively considerable.
Minerals and Energy Resources				
Impact 4.15-1: Construction-related energy use.	PSM	LS	Y	See Impact ME-1: The Project would not encourage activities that result in the use of large amounts of fuel and energy in a wasteful manner during construction. The PEIR identified a potentially significant impact related to energy use during construction. Because the GSR Project would not use large amounts of fuel and energy in a wasteful manner, the project-level analysis identified a less-than-significant impact.

TABLE D-2
WSIP PEIR Impacts Consistency

PEIR Impact	PEIR Significance Determination for San Francisco Region Groundwater Project SF-2	GSR Project-level Significance Determination	Same Rationale for Significance Determination as PEIR? (Y/N)	Notes: (Explain difference in significance determinations and/or rationale for determinations)
Impact 4.15-2: Long-term energy use during operation.	PSM	LS	N	See Impact ME-2: The Project would not encourage activities that result in the use of large amounts of fuel and energy in a wasteful manner during operation. The PEIR estimated that the PEIR Regional Groundwater Projects would require up to 5,100,000 kWh for operation. The PEIR determined that implementation in addition to other WSIP projects in the San Francisco region (e.g., San Andreas Pipeline 3 Installation and Recycled Water Project) would increase energy use in the San Francisco region by approximately 87 percent, a potentially significant impact. The project-level analysis determined that the collective change in energy demand of the new well facilities and Westlake Pump Station, the Partner Agencies' wells, and the regional water system would be negligible, and the GSR Project would not cause a substantial increase in energy use on a long-term basis. The impact was determined to be less than significant.
Impact 4.17-13: Cumulative increases in the use of nonrenewable energy resources.	LS	LS	N	See Impact C-ME-1: Construction and operation of the proposed Project would not result in a cumulatively considerable contribution to cumulative impacts related to mineral and energy resources. The PEIR determined that the WSIP's contribution to cumulative increases in long-term energy demand would not be considerable. The PEIR also determined that with implementation of exhaust control measures required in the Air Quality Section of the PEIR, the WSIP's contribution to the regionwide cumulative increase in construction-related energy consumption would not be considerable. The project-level analysis identified the potential for cumulative impacts from multiple construction projects in the same geographic region. The GSR Project's contribution to cumulative impacts would not be cumulatively considerable, as large amounts of fuel and energy would not be used in a wasteful manner during construction (less than significant).

TABLE D-2
WSIP PEIR Impacts Consistency

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Land Use		
Measure 4.3-2, Facility Siting Studies: Conduct project-specific facility siting studies for non-SFPUC land and implement these studies' recommendations to avoid or minimize impacts on existing land uses.	Y	This measure has been implemented. The SFPUC completed project-specific siting studies in the Final Alternatives Analysis Report to determine the most appropriate location of the 16 proposed and 3 alternate well facility sites. Wells would be located both on lands owned by the SFPUC or owned by others. Land use criteria used in the Alternatives Analysis Report included ownership and compatibility with local zoning were used to avoid or minimize impacts to existing nearby land uses.
Measure 4.3-4a, Architectural Design: Design permanent new, aboveground facilities to be compatible with existing visual character of the site and surrounding area.	Y	The proposed aboveground facilities would have a similar appearance as other SFPUC water supply facilities. Most well facilities are not visible from scenic resources and would not alter the visual character of the surrounding areas. Further, existing topography and vegetation would provide partial screening of many proposed aboveground facilities. Additional mitigation measures are included in the GSR EIR to reduce potential impacts to scenic resources and visual character. These measures include Mitigation Measures M-AE-1b (Tree Protection Measures), M-AE-1c (Develop and Implement at Tree Replanting Plan), M-AE-3a (Implement Landscape Screening), M-CR-5a (Minimize Facilities Siting Impacts on Elements of the Historical Resource at Site 14), and M-CR-5b (Minimize Facilities Siting Impacts on Elements of the Historical Resource at Site 15). These measures provide site-specific requirements in accordance with the PEIR mitigation measure.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.3-4b, Landscaping Plans: Prepare and implement landscaping plans to restore (recontour, revegetate, landscape) sites to preconstruction conditions. Monitor landscape plantings.	Y	This measure is implemented as part of the GSR Project for all proposed well facility sites. After construction is complete, well facility sites would be restored to their general pre-construction conditions, but in accordance with the SFPUC's Vegetation Management Policy (SFPUC 2007), they may be revegetated with alternate plantings. This approach replaces the requirement for preparation and implementation of a landscaping plan in accordance with the PEIR mitigation measure, except for Sites 4, 7, and 18 (Alternate) which require implementation of Mitigation Measure M-AE-3a (Implement Landscape Screening) to reduce impacts to less than significant levels. The Project Description for Sites 10 and 13 includes landscape plan requirements.
Measure 4.3-4c, Landscape Screens: Include new plantings and landscape berms to screen views of new structures and equipment from scenic roads.	Y	The proposed aboveground facilities would be similar in appearance as other SFPUC water infrastructure facilities in San Francisco and San Mateo counties. Most well facility sites would not be visible from scenic resources or from scenic roadways. Existing topography and vegetation would provide partial screening of many proposed aboveground facilities. The well facility at Site 15 (in Golden Gate National Cemetery) would be located along Sneath Lane which is designated as a scenic roadway by the City of San Bruno. Mitigation Measure M-AE-1d (Construction Area Screening) would screen the construction activities from views along Sneath Lane. Likewise, M-AE-3a (Implement Landscape Screening) would screen views of these sites from adjacent residences or cemeteries.
Measure 4.3-4d, Minimize Tree Removal: Minimize or avoid the removal of trees that screen existing and proposed WSIP facility sites; implement tree replacement plan.	Y	See GSR Mitigation Measures M-BR-4a (Identify Protected Trees) and BR-4b (Protected Tree Replacement). Additionally, M-AE-1b (Tree Protection Measures) and M-AE-1c (Develop and Implement a Tree Replanting Plan) would minimize tree removal along El Camino Real during construction of the pipeline for Site 12.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.3-5, Reduce Lighting Effects: Use cut-off shields and nonglare fixture design, direct lighting onsite and downward, prevent use of highly reflective building materials or finishes.	Y	As part of the GSR Project Description nighttime lighting during construction would be placed away from surrounding residences and light sensitive land uses. The Project includes the development of a site-specific construction lighting plan for sites where nighttime construction lighting would be needed. The site-specific lighting plans would include elements that would be in accordance with the PEIR mitigation measure.
Geology		
Measure 4.4-1, Quantified Landslide Analysis: Avoid sites with landslide hazards; where they cannot be avoided, conduct site-specific slope stability analyses and implement recommendations.	Y	Site-specific geotechnical evaluations were completed for most sites during conceptual design of the GSR Project. Mitigation Measure M-GE-3 (Conduct Site-Specific Geotechnical Investigations and Implement Recommendations) requires that the SFPUC conduct a site-specific design-level geotechnical study for all sites selected for construction as described in Impact GE-3 and GE-4. The measure requires that facilities be designed and constructed in conformance with the specific recommendations contained in the design-level geotechnical studies. This mitigation measure meets the requirement for preparation and implementation of an individual landslide analysis in accordance with the PEIR mitigation measure.
Measure 4.4-4, Subsidence Monitoring Program: Monitor subsidence and implement corrective actions as warranted.	N	The PEIR mitigation applies to ground subsidence related to tunneling. Although the GSR Project does not include tunneling, the Project EIR included an evaluation of the potential impacts from subsidence associated with groundwater pumping. GSR Project operations would not result in substantial land subsidence due to decreased groundwater levels in the Westside Groundwater Basin, and no mitigation would be needed to address subsidence impacts, as evaluated in Impact HY-7.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.4-9, Characterize Extent of Expansive and Corrosive Soil: Characterize the presence of expansive/corrosive soils; implement recommendations.	N	The presence of expansive and corrosive soils was evaluated as part of the site-specific geotechnical reports. The GSR Project would be constructed and designed in accordance with the recommendations of the site-specific geotechnical investigations to minimize the effects of any expansive soils. With incorporation of these design features, impacts related to expansive and corrosive soils would be less than significant and no mitigation is required. See Impact GE-5, The Project would not create significant risks to life or property due to expansive or corrosive soil; no mitigation would be required based on the site-specific geotechnical evaluations.
Hydrology and Water Quality		
Measure 4.5-2, Site-Specific Groundwater Analysis and Identified Measures: Conduct project-specific analysis of dewatering and implement measures to ensure that groundwater resources and the beneficial uses of groundwater are not adversely affected.	Y	See Impact HY-2. Mitigation Measure M-HY-2 (Management of Well Development and Pump Testing Discharges) would be necessary to address potential impacts to receiving waters from the discharge of dewatering effluent from well testing, including groundwater protection.
Measure 4.5-4a, Flood Flow Protection Measures: Preclude exposure of stockpiled soils, hazardous materials, and construction materials to flood flows.	Y	The proposed GSR Project construction staging areas are located outside of the designated 100-year FEMA flood hazard zone. Mitigation Measure M-HY-1 (Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan) would require that the construction contractor implement site-specific BMPs to protect water quality during project construction activities. No additional mitigation is necessary.
Measure 4.5-4b, Site-Specific Flooding Analysis and Identified Measures: Implement design measures to preclude projects from causing flooding or damage from redirected flood flows.	Y	GSR Project construction would not result in flooding impacts associated with impeding or redirecting flood flows as the Project would be located outside of the designated 100-year FEMA flood hazard zone, as analyzed in the evaluation of impacts under Impact HY-3.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.5-5, **Stormwater Treatment and Groundwater Monitoring:** If treated stormwater is used to maintain Lake Merced water levels, monitor surface water and groundwater quality in the vicinity of Lake Merced. Identify and implement corrective actions (e.g., treatment).	Y	The GSR Project would not discharge treated stormwater into a lake directly, however implementation of Mitigation Measures M-HY-9a (Lake Level Monitoring and Modeling for Lake Merced) and M-HY-9b (Lake Level Management for Lake Merced) would require the SFPUC to implement a lake level management program, including lake level and water quality monitoring and groundwater level elevations. The measures would require the addition of supplemental water to augment lake levels if available; and alter pumping as necessary to avoid adverse effects on Lake Merced should a supplemental water source be unavailable. Supplemental water may include treated stormwater. Mitigation Measure M-HY-9a requires monitoring for both surface water and groundwater quality at Lake Merced.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.5-6, Appropriate Source Controls and Site Design Measures: For projects located in areas not covered by a municipal stormwater permit and disturbing less than one acre of land during construction, implement appropriate source control and site design measures. These measures will ensure compliance with applicable water quality criteria and goals and protect the beneficial uses of the receiving water.	Y	Earthmoving activities associated with GSR Project construction would temporarily alter existing drainage patterns at well facility sites, including vegetation removal, grading, excavation and soil stockpiling. Construction activities could also result in the accidental release of hazardous construction chemicals, such as adhesives, solvents and fuels. If not managed appropriately, these chemicals could adhere to soil particles, become mobilized by rain or runoff, or infiltrate into groundwater, degrading water quality. Mitigation Measure M-HY-1 (Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan) would reduce water quality impacts during Project construction activities. Consistent with the requirements of the NPDES General Permit for Storm Water Discharges Associated with Construction Activity, at sites where more than one acre of land disturbance would occur (Sites 3, 4, 5, 6, 7, 12, 13, and 14), the SFPUC or its contractor(s) would develop a Storm Water Pollution Prevention Plan (SWPPP), submit a notice of intent to the SWRCB's Division of Water Quality and implement site-specific BMPs to prevent discharges of nonpoint-source pollutants in construction-related stormwater runoff into downstream water bodies. At sites where less than one acre of land disturbance would occur (Sites 1, 2, 8, 9, 10, 11, 15, 16, 17 Alternate, 18 Alternate, and 19 Alternate), the SFPUC or its contractor(s) would prepare and implement Erosion and Sediment Control Plans (ESCPs). The ESCP would include measures to address the overall construction of the Project and to minimize any adverse effects on water quality. This mitigation measure meets the requirement for compliance with water quality standards and to protect the beneficial uses of receiving waters in accordance with the PEIR mitigation measure.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 5.6-1, Groundwater Monitoring to Determine Basin Safe Yield: The SFPUC will continue ongoing studies, including the existing groundwater and lake level monitoring programs, to determine the safe yield of the North Westside Groundwater Basin in order to avoid overdraft and associated effects including adverse effects on surface water features and seawater intrusion. Using this data, the SFPUC will develop and implement a plan identifying appropriate pumping patterns to avoid overdraft and the undesirable effects associated with overdraft. The plan will establish both a regular (average annual) and an intermittent (dry year or emergency) yield as well as a strategy for modifying pumping patterns such that the pumping levels can be sustained as an ongoing reliable water supply without depletion of groundwater storage or degradation of water quality.	N	This mitigation measure only applies to projects in the North Westside Groundwater Basin. The GSR Project would be in the South Westside Groundwater Basin. Nevertheless, the GSR Project may cause significant impacts relative to groundwater depletion, which would be reduced to less than significant through implementation of Mitigation Measures M-HY-14 (Prevent Groundwater Depletion). The mitigation measure includes provisions that GSR wells shall only be pumped when there is a positive balance in the SFPUC Storage Account, which will be adjusted for losses from the Basin due to leakage caused as a result of the Project.
Measure 5.6-2, Implementation of a Lake Level Management Plan: The SFPUC will develop and implement a lake level management plan identifying strategies for altering pumping patterns or lake augmentation to maintain Lake Merced water levels within the desired long-term range should monitoring conducted under Measure 5.6-1 indicate the potential for adverse effects on lake levels due to groundwater pumping. The SFPUC will coordinate the implementation of this measure with Measure 5.6-1.	N	This mitigation measure is only applicable to projects in the North Westside Groundwater Basin. The GSR Project would be in the South Westside Groundwater Basin. Nevertheless, the GSR Project may cause significant impacts on Lake Merced water levels, which would be reduced to less than significant through implementation of Mitigation Measures M-BR-7 (Lake Level Management for Water Levels Increases for Lake Merced), M-HY-9a (Lake Level Monitoring and Modeling for Lake Merced) and M-HY-9b (Lake Level Management for Lake Merced). These mitigation measures include monitoring and provisions to manage both increasing and decreasing Lake Merced lake levels to the extent such lake level changes are caused by the Project.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 5.6-5, Drinking Water Source Assessments for Groundwater Wells: As required by the California Department of Health Services and incorporated as part of the WSIP, the SFPUC will prepare drinking water source assessments for groundwater wells constructed under the Local and Regional Groundwater Projects (SF-2) and will update these assessments every five years. If the assessment indicates no potential for contamination, then no mitigation is required. However, for wells that are considered vulnerable to contamination on the basis of the drinking water source assessment, the SFPUC will develop and implement a source water protection program specifying actions and a program to be implemented to prevent contamination of the drinking water source. The source water protection program could include nonregulatory components such as watershed restoration, stormwater monitoring, groundwater monitoring, and public education to protect drinking water quality. Land use planning, permitting, and possibly more restrictive regulatory methods may also be implemented by the local municipality where a threat to drinking water quality is indicated, and management of potential sources of microbiological or direct chemical contamination to eliminate or reduce the risk of contamination of the water supply may be considered. The SFPUC will encourage public participation in the development of the program and will update the program every five years along with the drinking water source assessments.	Y	Preliminary Drinking Water Source Assessment and Protection Program (DWSAP) reports for most well sites were prepared by the SFPUC as part of the conceptual design of the GSR Project. The preliminary DWSAPs indicate that groundwater at these sites may be vulnerable to contamination from nearby land use activities. However, the analysis of the site-specific conditions in Impact HY-12 concluded that, in the South Westside Groundwater Basin, known contamination is located near the ground surface, the GSR wells would be screened from 240 feet to 700 feet below ground surface, and the Primary Production Aquifer where the GSR wells would be pumping from is generally disconnected hydraulically from most occurrences of shallow groundwater zones. In addition, the GSR Project would decrease the downward gradient over the long term, therefore decreasing the risk of contamination. Therefore, the analysis concludes that impacts relative to contamination of the drinking water source would be less than significant, and no mitigation would be required.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Biology		
Measure 4.6-1a, Wetlands Assessment: Wetland scientist will determine whether wetlands could be affected by the project, and, if so, perform a wetland delineation and develop mitigation.	N	See Impacts BR-3 and BR-8. A wetlands assessment was performed in support of the Project-level analysis, which included an evaluation of potential effects on wetland habitats at Lake Merced. Although no wetlands or open waters regulated under federal or State law would be directly impacted by the Project, Mitigation Measure M-HY-1 (Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan) would be implemented to protect surrounding waterways from construction-related runoff and sedimentation, reducing potential indirect impacts to less than significant. Implementation of Mitigation Measures M-BR-8 (Lake Level Management for No-Net-Loss of Wetlands for Lake Merced), and Mitigation Measures M-HY-9a (Lake Level Monitoring and Modeling for Lake Merced) and M-HY-9b (Lake Level Management for Lake Merced) would reduce potential Project impacts on wetlands at Lake Merced to less-than-significant levels.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.6-1b, Compensation for Wetlands and Other Biological Resources: If a WSIP project will affect jurisdictional wetlands, implement avoidance measures, restoration procedures, and compensatory creation or enhancement to ensure no net loss of wetland extent or function. Compensate for sensitive riparian and upland habitats supporting key special-status species. Obtain permits for each project and comply with applicable regulations addressing sensitive habitats and species. The Habitat Reserve Program is an alternative for implementing offsite habitat compensation.	Y	No wetlands or open waters regulated under federal or State law would be directly impacted by the GSR Project; however, Mitigation Measure M-HY-1 (Develop and Implement a Storm Water Pollution Prevention Plan [SWPPP] or an Erosion and Sediment Control Plan) would be implemented to protect surrounding waterways from construction-related runoff and sedimentation, reducing potential indirect impacts to less than significant. Implementation of Mitigation Measures M-BR-8 (Lake Level Management for No-Net-Loss of Wetlands for Lake Merced), and Mitigation Measures M-HY-9a (Lake Level Monitoring and Modeling for Lake Merced) and M-HY-9b (Lake Level Management for Lake Merced) would reduce potential Project impacts on wetlands at Lake Merced to less-than-significant levels. See also Mitigation Measure M-BR-2 (Avoid Disturbance to Riparian Habitat), which would require the avoidance of riparian habitat. The mitigation measure requires installation of temporary fencing to demarcate the boundary for construction at these sites. This mitigation measure is consistent with the PEIR mitigation measure and is specific to the Project requirements. Therefore, no wetland impacts would require compensatory mitigation.
Measure 4.6-2, Habitat Restoration/Tree Replacement: Restore temporarily affected sensitive habitats. Replace trees designated as heritage trees (or similar local designation) consistent with requirements of local ordinances. Minimize loss of sensitive habitats by coordinating WSIP projects.	Y	See Mitigation Measures M-BR-4a (Identify Protected Trees) Mitigation Measure M-AE-1b (Tree Protection Measures), and Mitigation Measure M-BR-4b (Protected Tree Replacement). The project-level mitigation measures require implementation of protective measures to avoid or minimize impacts on mature native trees during construction, and if removal is necessary, to plant replacement trees at or in close proximity to the removal sites to the extent feasible. If replanting trees on the same location is not feasible or could result in damage to the proposed improvements, the SFPUC shall designate a suitable planting site elsewhere in the Project area. These mitigation measures are consistent with the PEIR mitigation measure and are specific to the GSR Project requirements.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)		Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.6-3a, Protection Measures During Construction for Key Special-Status Species and Other Species of Concern: Where key special-status species and other species of concern are potentially present, implement general practice measures (preconstruction surveys, worker awareness program, environmental inspector, minimization of habitat loss).		Y	See Mitigation Measures M-BR-1a (Protection Measures during Construction for Special-status Birds and Migratory Passerines and Raptors), M-BR-1b (Protection Measures for Special-status Bats during Tree Removal or Trimming), and M-BR-1d (Monarch Butterfly Protection Measures). The project-level measures are consistent with the PEIR measure and provide additional site- and project-specific details where key special-status species and other species of concern are potentially present. These mitigation measures are consistent with the PEIR mitigation measure and are specific to the GSR Project requirements.
Measure 4.6-3b, Standard Mitigation Measures for Key Special-Status Plants and Animals: Implement measures to reduce impacts on key special-status species. *See below for specific species and corresponding sub-PEIR mitigation number.*			
Invertebrates			
Valley Elderberry Longhorn Beetle	I.1	N	Species not identified in GSR Project vicinity.
Vernal Pool Crustaceans (Vernal Pool Fairy Shrimp; Conservancy Fairy Shrimp; Vernal Pool Tadpole Shrimp)	I.2	N	Species not identified in GSR Project vicinity.
Bay Checkerspot Butterfly; Callippe Silverspot Butterfly	I.3	N	Species not identified in GSR Project vicinity.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)		Applicable to Proposed Project (Y/N)?	Discussion
Fish			
Central Valley Fall- and Late-Fall-Run DPS Chinook Salmon; Central Valley DPS Steelhead; Green Sturgeon Southern District DPS; Central Coast DPS Steelhead; Rainbow Trout	F.1	N	Species not identified in GSR Project vicinity.
Reptiles and Amphibians			
California Red-Legged Frog; Foothill Yellow-Legged Frog	RA.1	N	Species not identified in GSR Project vicinity.
California Tiger Salamander	RA.2	N	Species not identified in GSR Project vicinity.
San Francisco Garter Snake	RA.3	N	Species not identified in GSR Project vicinity.
Alameda Whipsnake	RA.4	N	Species not identified in GSR Project vicinity.
Birds			
Swainson's Hawk	B.1	N	Species not identified in GSR Project vicinity.
Western Burrowing Owl	B.2 and B.3	N	Species not identified in GSR Project vicinity.
Raptors (including Bald Eagle)	B.4	Y	See Mitigation Measure M-BR-1a (Protection Measures during Construction for Special-status Birds and Migratory Passerines and Raptors).
Least Bell's Vireo	B.5	N	Species not identified in GSR Project vicinity.
California Black Rail, California Clapper Rail	B.6	N	Species not identified in GSR Project vicinity.
Western Snowy Plover	B.7	N	Species not identified in GSR Project vicinity.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)		Applicable to Proposed Project (Y/N)?	Discussion
Mammals			
Salt Marsh Harvest Mouse	M.1	N	Species not identified in GSR Project vicinity.
San Joaquin Kit Fox	M.2	N	Species not identified in GSR Project vicinity.
Riparian Woodrat	M.3	N	Species not identified in GSR Project vicinity.
Vernal Pool Plants			
Succulent Owl's Clover; Hoover's Spurge; Colusa Grass; San Joaquin Valley Orcutt Grass; Greene's Tuctoria; Hairy Orcutt Grass)	P.1	N	Species not identified in GSR Project vicinity.
Riparian Plants			
Delta Button-Celery	P.2	N	Species not identified in GSR Project vicinity.
Large-Flowered Fiddleneck	P.3	N	Species not identified in GSR Project vicinity.
San Francisco Woolly Sunflower; Marin Western Flax; Fountain Thistle	P.4	N	Species not identified in GSR Project vicinity.
Measure 4.6-4, Pipeline and Water Treatment Plant Treated Water Discharge Restrictions: Design planned discharges from the WSIP pipelines and water treatment plants to natural water bodies to minimize impacts on riparian and aquatic resources and to avoid or minimize temperature effects on aquatic resources.		N	The project-level analysis determined that mandatory compliance with the Waste Discharge Requirements for the SFPUC Drinking Water Transmission System and SFPUC Standard Operating Protocols would ensure that water quality impacts due to discharges of treated water from existing and newly installed pipelines during construction would be less than significant. Planned discharges of groundwater during well maintenance activities would be sent to either the local sanitary sewer system or the storm drain system. Planned discharges to the storm drain system would be dechlorinated and pH adjusted prior to discharge, so that eventual discharge to a surface water from the storm drain would not impact riparian and aquatic resources.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Cultural		
Measure 4.7-1, Suspend Construction Work if Paleontological Resource Is Identified: Suspend work and notify a qualified paleontologist when a paleontological resource is discovered at any of the project sites. The paleontologist will document the discovery as needed, evaluate the potential resource, and assess the significance of the find under CEQA criteria. Temporarily halt or divert excavation within 50 feet of a fossil find until the discovery is examined by a paleontologist. If avoidance is not feasible, the paleontologist will prepare an excavation plan.	Y	The project-level measures specify more stringent requirements than the PEIR measure due to the high potential to encounter paleontological resources during construction. Specific requirements include a paleontological resources training for construction workers, a paleontological resources monitoring program, and assessment and salvage of fossil finds, as applicable. See Mitigation Measure M-CR-3 (Suspend Construction Work if a Paleontological Resource is Identified).
Measure 4.7-2a, Archaeological Testing, Monitoring, and Treatment of Human Remains: Determine if implementation of an archaeological testing or archaeological monitoring program or both is the appropriate strategy for avoidance of potential adverse effects on significant archaeological resources. Review any requirements approved by the State Historic Preservation Officer. Prepare an archaeological testing plan, archaeological monitoring plan, final archeological resources report and, if applicable, an archaeological data recovery plan. The treatment of human remains and of associated or unassociated funerary objects discovered during any soil-disturbing activity will comply with applicable state laws.	Y	Although no known human burial locations have been identified within the GSR Project area, the EIR measure addresses the possibility of discovery during construction activities. See Mitigation Measure M-CR-4 (Accidental Discovery of Human Remains).

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.7-2b, Accidental Discovery Measures: Distribute archaeological resource "ALERT" sheet to contractors. If an archaeological resource may be present within the project site, an archaeological consultant will evaluate it and make a recommendation as to what action (e.g., preservation in situ) is warranted. The SFPUC will implement appropriate measures.	Y	No archaeological sites were identified within any of the GSR Project construction areas. However, at Site 11, there is some potential that remnants of a known archaeological site may still exist. See Mitigation Measure M-CR-2 (Discovery of Archaeological Resources). This mitigation measure requires the SFPUC and its contractors to adhere to appropriate procedures and protocols for minimizing impacts on any previously unrecorded and buried (or otherwise obscured) archaeological deposits, in the event that a possible archaeological resource is discovered during construction activities. This mitigation measure is consistent with the PEIR mitigation measure and is specific to the Project requirements.
Measure 4.7-3, Protection of Historic Districts: A qualified historian will assess the city's water system facilities affected by WSIP facility projects for their potential contribution to a historic district. If a historic district would be affected by one or more proposed WSIP facility project(s), develop and implement mitigation measures for effects with attention to the potential district as a whole. If a historic district is identified at the project level, it should be recorded as such, using National/California Register criteria of significance. Document the district by completing the State of California Department of Parks and Recreation Form 523 and submit to the State Historic Preservation Officer.	N	The GSR Project would not affect any portion of the City's water system facilities, except connection to underground pipelines, which would have no adverse effect on any potential historic district associated with the City's water system facilities.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.7-4a, Alternatives Identification and Resource Relocation: Identify feasible project alternatives to eliminate or reduce the need for demolition or removal of a historic resource to the greatest extent possible. If preservation of the affected historical resource at the current site is determined to be infeasible, the structure will be stabilized and relocated to other appropriate nearby sites, if feasible. After relocation, the resource will be treated according to the Secretary of the Interior's *Standards for the Treatment of Historic Properties*. If the affected historic resource is to be demolished, consult with local historical societies and governmental agencies regarding salvage of materials for public information or reuse in other locations.	N	The project-level measures are consistent with the PEIR measure and provide additional site- and project-specific details to protect historic resources at Sites 14 and 15. No other proposed GSR well facility sites would have significant impacts on historic resources. These mitigation measures are consistent with the PEIR mitigation measure and are specific to the Project requirements. See Mitigation Measure M-CR-5a (Minimize Facilities Siting Impacts on Elements of the Historical Resources at Site 14) and Mitigation Measure M-CR-5b (Minimize Facilities Siting Impacts on Elements of the Historical Resources at Site 15).
Measure 4.7-4b, Historical Resources Documentation: Prepare documentation of historic resources prior to any construction work associated with demolition or removal. The appropriate level of documentation will be selected by a qualified professional who meets the standards for history, architectural history, and/or architecture (as appropriate) set forth by the Secretary of the Interior's *Professional Qualification Standards* (36 CFR 61) in consultation with a preservation specialist assigned by the San Francisco Planning Department and the local jurisdiction, if deemed appropriate by the Planning Department.	N	As part of the GSR EIR analysis, an architectural historian, who meets the standards set for by the Secretary of Interior's Standards, was retained to evaluate impacts to historic resources. The evaluation identified significant impacts only at Sites 14 and 15. See Mitigation Measure M-CR-5a (Minimize Facilities Siting Impacts on Elements of the Historical Resources at Site 14) and Mitigation Measure M-CR-5b (Minimize Facilities Siting Impacts on Elements of the Historical Resources at Site 15).

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.7-4c, Secretary of the Interior's Standards for the Treatment of Historic Properties: Prepare materials describing and depicting the proposed project. Review the proposed project for compliance with the Secretary of the Interior's *Standards for the Treatment of Historic Properties*. If a project is determined to be inconsistent with the *Standards for the Treatment of Historic Properties*, pursue and implement redesign of the project such that consistency with the standards is achieved.	Y	The project-level measures are consistent with the PEIR measure and provide additional site- and project-specific details to protect historic resources at Sites 14 and 15. No other proposed GSR well facility sites would have significant impacts on historic resources. These mitigation measures are consistent with the PEIR mitigation measure, are specific to the Project requirements, and reduce impacts to less than significant under CEQA. See Mitigation Measure M-CR-5a (Minimize Facilities Siting Impacts on Elements of the Historical Resources at Site 14) and Mitigation Measure M-CR-5b (Minimize Facilities Siting Impacts on Elements of the Historical Resources at Site 15).
Measure 4.7-4d, Historic Resources Survey and Redesign: Undertake a historic resources survey to identify and evaluate potential historic resources that may exist in the project's area of potential effect. If a survey identifies one or more historical resources, assess the impact the project may have on those historical resources. If the project will cause a substantial adverse change to a historic resource, assign a preservation specialist to review the proposed project for compliance with the Secretary of the Interior's *Standards for the Treatment of Historic Properties*. If the project is determined to be inconsistent with those standards, pursue and implement redesign of the project such that consistency with the standards is achieved.	Y	As part of the GSR EIR analysis, a historic resources survey was undertaken within the Project's area of potential effect. The resources that were identified were evaluated, and significant impacts were identified at Sites 14 and 15. These mitigation measures are consistent with the PEIR mitigation measure, are specific to the Project requirements, and reduce impacts to less than significant under CEQA. See Mitigation Measure M-CR-5a (Minimize Facilities Siting Impacts on Elements of the Historical Resources at Site 14) and Mitigation Measure M-CR-5b (Minimize Facilities Siting Impacts on Elements of the Historical Resources at Site 15).

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.7-4e, Historic Resources Protection Plan: A qualified historian will prepare a plan that specifies procedures for protecting and monitoring historic resources during construction.	Y	The project-level measures are consistent with the PEIR measure and provide additional site- and project-specific details to protect historic resources at Sites 14 and 15. No other proposed GSR well facility sites would have significant impacts on historic resources. These mitigation measures are consistent with the PEIR mitigation measure and are specific to the Project requirements. See Mitigation Measure M-CR-5a (Minimize Facilities Siting Impacts on Elements of the Historical Resources at Site 14) and Mitigation Measure M-CR-5b (Minimize Facilities Siting Impacts on Elements of the Historical Resources at Site 15), which include monitoring of potential impacts on historic resources during construction.
Measure 4.7-4f, Preconstruction Surveys and Vibration Monitoring: Include geotechnical investigations if vibration-related impacts could affect historic resources. Follow recommendations of the final geotechnical reports. Conduct a preconstruction survey of existing conditions and monitor the adjacent buildings for damage during construction, if recommended.	Y	See Impact NO-2. The project-level analysis determined that construction-related groundborne vibration would be below the significance thresholds, except at Site 15, which is located within a potential historic district, because of nearby pipeline construction. See Mitigation Measure M-NO-2 (Reduce Vibration Levels during Construction of Pipelines).

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Traffic		
Measure 4.8-1a, Traffic Control Plan Measures: Elements of the traffic control plan could include: circulation and detour plans, designated truck routes, sufficient staging area, access to driveways, use of standard construction specifications for controlling construction vehicle movements, restrictions on truck trips during peak morning and evening commute hours, lane closure restrictions, maintenance of alternate one-way traffic flow, detour signing, pedestrian and bicycle access and circulation, equipment and materials storage, construction worker parking, roadside safety protocols, considerations for sensitive land uses, coordination with local transit service providers, roadway repair, and conformance with the state's *Manual of Traffic Controls for Construction and Maintenance Work Areas*.	Y	See Mitigation Measure M-TR-1 (Traffic Control Plan). The project-level mitigation measure has been tailored to specify those elements appropriate to the proposed Project. The mitigation measure specifies that traffic control plans conform to the applicable provisions of the state's *Manual of Traffic Controls for Construction and Maintenance Work Areas.*
Measure 4.8-1b, Coordination of Individual Traffic Control Plans: In the event that more than one construction contract is issued for work along existing or new pipelines, and where construction could occur within and/or across multiple streets in the same vicinity, coordinate the traffic control plans in order to mitigate the impact of traffic disruption by including measures that address overlapping construction schedules and activities, truck arrivals and departures, lane closures and detours, and the adequacy of on-street staging requirements.	Y	See Mitigation Measure M-C-TR-1 (Coordinate Traffic Control Plan with other SFPUC Construction Projects). The mitigation measure specifies that the SFPUC and its construction contractors shall coordinate traffic control plans for overlapping construction.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.8-4, Accommodation of Displaced Public Parking Supply for Recreational Visitors: Include an additional measure in the traffic control plans to accommodate any anticipated visitor parking demand that would be displaced by proposed projects at public recreational facilities.	N	No recreational parking would be displaced under the GSR Project.
Air Quality		
Measure 4.9-1a, SJVAPCD Dust Control Measures: Include San Joaquin Valley Air Pollution Control District (SJVAPCD) Basic Control Measures in contract specifications for all construction sites. Include SJVAPCD Enhanced Control Measures in contract specifications when required to mitigate significant PM10 impacts. Include SJVAPCD Additional Control Measures in contract specifications for construction sites that are large in area, located near sensitive receptors, or which for any other reason warrant additional emissions reductions. Include SJVAPCD Rule 9510, Indirect Source Review, Section 6.1, Construction Equipment Emissions in contract specifications for any project subject to discretionary approval by a public agency that ultimately results in the construction of a new building, facility, or structure or reconstruction of a building, facility, or structure for the purpose of increasing capacity or activity and also involving 9,000 square feet of space.	N	The GSR Project would not be located within the jurisdiction of the SJVAPCD.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.9-1b, SJVAPCD Exhaust Control Measures: Include SJVAPCD Exhaust Control Measures in contract specifications, where applicable, for heavy-duty equipment to limit exhaust emissions within the San Joaquin Region.	N	The GSR Project would not be located within the jurisdiction of the SJVAPCD.
Measure 4.9-1c, BAAQMD Dust Control Measures: For projects in the Sunol Valley, Bay Division, Peninsula, and San Francisco Regions, include Bay Area Air Quality Management District (BAAQMD) Basic Control Measures in contract specifications for all construction sites. Include BAAQMD Enhanced Control Measures in contract specifications for sites over four acres. Include BAAQMD Optional Control Measures in contract specifications for sites that are large in area, located near sensitive receptors, or which for any other reason warrant additional emissions reductions.	Y	See Mitigation Measure M-AQ-2a (BAAQMD Basic Construction Measures [All Sites]). The project-level mitigation is consistent with the BAAQMD guidelines and significance thresholds utilized in the GSR Project EIR for assessing and mitigating air quality impacts.
Measure 4.9-1d, BAAQMD Exhaust Control Measures: For projects in the Sunol Valley, Bay Division, Peninsula, and San Francisco Regions, include BAAQMD Exhaust Control Measures to limit exhaust emissions, where applicable.	Y	See Mitigation Measure M-AQ-2b (NOx Reduction during Construction of Alternate Sites). The project-level mitigation is consistent with the BAAQMD guidelines and the significance thresholds utilized in the GSR Project EIR for assessing and mitigating air quality impacts.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.9-2a, Health Risk Screening or Use of Soot Filters: Complete a health risk screening if truck volumes associated with a particular project along a particular haul route exceed 40,000 truck trips over the entire construction period. If a potentially significant impact is indicated, complete a site-specific health risk assessment. Consider diesel particulate matter (DPM) emission rates in separate project-level analysis at the time of construction. Develop a mitigation program based on the site-specific health risk assessment implementing methods of reducing DPM emission or exposure to a less-than-significant level.	Y	The health risk assessment conducted as part of the GSR EIR analysis determined that DPM exposure exceeded the BAAQMD's cancer and non-cancer risk thresholds, utilized as significance in the GSR EIR, at Group 3 for Sites 5, 6, and 7 (On-site Treatment). Mitigation Measure M-AQ-3 (Construction Health Risk Mitigation) would be implemented to reduce construction emissions to less-than-significant levels, as discussed in GSR Section 5.8, Air Quality under Impact AQ-3.
Measure 4.9-2b, Vacate SFPUC Land Managers' Residences in Sunol Valley: Vacate the two SFPUC Land Managers' residences in the Sunol Valley during construction of the Calaveras Dam or SVWTP – Treated Water Reservoirs projects or complete a health risk screening (and, if warranted, a health risk assessment) to determine health risks at these residences from either of these two projects.	N	The GSR Project would not be located in Sunol Valley.
Measure 4.9-3, Tunnel Gas Odor Control: Add water scrubbers and appropriate chemicals to tunnel ventilation systems if odorous gases become a nuisance odor problem (i.e., odor complaints are received).	N	The GSR Project would not include tunneling.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Noise/Vibration		
Measure 4.10-1a, Noise Controls: For all WSIP projects located within 500 feet of any noise-sensitive receptors, implement appropriate noise controls to reduce daytime construction noise levels to meet the 70-dBA daytime speech interference criterion to the extent feasible. For all WSIP projects involving nighttime construction and located within 3,000 feet of any noise-sensitive receptors, implement appropriate noise controls to maintain noise levels at or below any applicable ordinance nighttime noise limits or the 50-dBA nighttime sleep interference criterion to the extent feasible.	Y	See Impact NO-1. Mitigation Measure M-NO-1 (Noise Control Plan) requires the SFPUC to retain a qualified noise consultant to prepare a Noise Control Plan and the SFPUC will approve the Noise Control Plan and ensure that it is implemented to ensure compliance with local noise ordinances to the extent feasible. However, under the GSR Project, even with implementation of this mitigation measure, the conflict with a local ordinance from required daytime construction and nighttime drilling and pump-testing at some well sites would be significant and unavoidable. See also Impact NO-3. Mitigation Measure M-NO-3 (Expanded Noise Control Plan) requires the SFPUC to retain a qualified noise consultant to prepare a Noise Control Plan and the SFPUC will approve the Noise Control Plan and ensure that it is implemented to reduce construction noise levels at nearby noise-sensitive land uses to meet the 70-dBA daytime and 50-dBA nighttime criteria to the extent feasible. However, even with implementation of this mitigation measure, the impact from required daytime construction and nighttime drilling and pump-testing at some well sites would be significant and unavoidable.
Measure 4.10-1b, Vacate SFPUC Caretaker's Residence at Tesla Portal: Vacate caretaker's residence at Tesla Portal during construction of the Advanced Disinfection and Tesla Portal Disinfection Station projects as well as those portions of the San Joaquin Pipeline System and Rehabilitation of Existing San Joaquin Pipelines projects located at Tesla Portal.	N	The GSR Project would not be located at the Tesla Portal.
Measure 4.10-2a, Limit Hourly Truck Volumes: Haul and delivery truck routes for all WSIP projects will, to the extent feasible, avoid local residential streets and follow local designated truck routes. Total project-related haul and delivery truck volumes on any particular haul truck route will be limited to 80 trucks per hour.	N	See Impact NO-4. Construction-related vehicle trips would not result in substantial temporary increases in ambient noise levels along construction access routes. Although the GSR Project requires construction in residential areas and along residential streets, anticipated hourly truck volumes would not result in a significant impact, and no mitigation would be needed.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.10-2b, Restrict Truck Operations: Prohibit haul and delivery trucks from operating within 200 feet of any residential uses during the nighttime hours. For receptors beyond 200 feet from a haul route, limit noise levels to the 50-dBA sleep interference criterion at the closest receptor.	N	See Impact NO-4. Although there are residential uses within 200 feet of several proposed GSR sites, construction-related vehicle trips would not result in substantial temporary increases in ambient noise levels along construction access routes, because haul and delivery trucks would not be used during nighttime hours.
Measure 4.10-2c, Vacate SFPUC Land Manager's Residence: Vacate Land Manager's residence adjacent to Alameda East Portal during offsite truck operations associated with the New Irvington Tunnel project, if truck operations occur during the nighttime hours (10 p.m. to 7 a.m.) and are estimated to exceed the 50-dBA sleep interference criterion at this residence.	N	The GSR Project would not be located near the SFPUC Land Manager's Residence.
Measure 4.10-3a, Vibration Controls to Prevent Cosmetic or Structural Damage: Incorporate restrictions into all contract specifications (primarily for sheetpile driving, pile driving, or tunnel construction activities), whereby surface vibration will be limited to 0.2 inch/second peak particle velocity (PPV) for continuous vibration (e.g., vibratory equipment and impact pile drivers) and 0.5 inch/second PPV for controlled detonations at the closest receptors to ensure that cosmetic or structural damage does not occur.	Y	See Impact NO-2. The project-level analysis determined that construction-related groundborne vibration would be below the significance thresholds except for Sites 3, 4, 12, 15, and 18 (Alternate). Mitigation Measure M-NO-2 (Reduce Vibration Levels during Construction of Pipelines) would apply to these sites.
Measure 4.10-3b, Limit Vibration Levels At or Below Vibration Perception Threshold: Maintain vibration levels at or below the vibration perception threshold at adjacent properties to the extent feasible during nighttime. If vibration complaints are received, operational adjustments will be made to reduce vibration annoyance effects.	Y	See Impact NO-2. The project-level analysis determined that construction-related groundborne vibration would be below the significance thresholds except for Sites 3, 4, 12, 15, and 18 (Alternate). Mitigation Measure M-NO-2 (Reduce Vibration Levels during Construction of Pipelines) would apply to these sites.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.10-3c, Limit Tunnel-Related Detonation to Daylight Hours: Limit controlled detonation associated with tunnel construction to daylight hours, Monday through Saturday.	N	The GSR Project would not include tunneling.
Services/Utilities		
Measure 4.11-1a, Notify Neighbors of Potential Utility Service Disruption: Notify residents and businesses in project area of potential utility service disruption two to four days in advance of construction.	Y	See Impact UT-1. GSR Project construction may result in temporary utility service disruption for residences or businesses. Mitigation Measure M-UT-1e (Advance Notification) requires two- to four-day advanced notice for all disruptions.
Measure 4.11-1b, Locate Utility Lines Prior to Excavation: Locate overhead and underground utility lines prior to excavation work.	Y	See Mitigation Measures M-UT-1a (Confirm Utility Line Information) and M-UT-1b (Safeguard Employees from Potential Accidents Related to Underground Utilities).
Measure 4.11-1c, Confirmation of Utility Line Information: Find the exact location of underground utilities by safe and acceptable means. Confirm information regarding the size, color, and location of existing utilities before construction activities commence.	Y	See Mitigation Measures M-UT-1a (Confirm Utility Line Information) and M-UT-1b (Safeguard Employees from Potential Accidents Related to Underground Utilities).
Measure 4.11-1d, Safeguard Employees from Potential Accidents Related to Underground Utilities: While any excavation is open, protect, support, or remove underground utilities as necessary to safeguard employees.	Y	See Mitigation Measures M-UT-1a (Confirm Utility Line Information) and M-UT-1b (Safeguard Employees from Potential Accidents Related to Underground Utilities).
Measure 4.11-1e, Notify Local Fire Departments: Notify local fire departments any time damage to a gas utility results in a leak or suspected leak, or whenever damage to any utility results in a threat to public safety.	Y	See Mitigation Measure M-UT-1d (Emergency Response Plan).

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.11-1f, Emergency Response Plan: Develop an emergency response plan in the event of a leak or explosion prior to commencing construction activities.	Y	See Mitigation Measure M-UT-1d (Emergency Response Plan).
Measure 4.11-1g, Prompt Reconnection of Utilities: Promptly reconnect any disconnected utility lines.	Y	See Mitigation Measures M-UT-1a (Confirm Utility Line Information) and M-UT-1b (Safeguard Employees from Potential Accidents Related to Underground Utilities).
Measure 4.11-1h, Coordinate Final Construction Plans with Affected Utilities: Coordinate final construction plans and specifications with affected utilities.	Y	See Mitigation Measures M-UT-1a (Confirm Utility Line Information) and M-UT-1b (Safeguard Employees from Potential Accidents Related to Underground Utilities).
Measure 4.11-2, Waste Reduction Measures: Incorporate into contract specifications for each WSIP project the requirement to obtain any necessary waste management permits prior to construction and to comply with conditions of approval attached to project implementation.	N	See Mitigation Measure M-UT-4 (Waste Management Plan).
Recreation		
Measure 4.12-1, Coordination with Golf Course/Recreational Facility Managers: Coordinate with managers of golf courses or other recreational facilities directly affected by pipeline construction to minimize adverse impacts on golfers and other recreational users.	N	The GSR Project Description includes notification of the Jefferson Elementary School District (which includes athletic fields used for recreation) a minimum of nine months prior to construction at school sites. The Project also includes obtaining easements from the Lake Merced Golf Club for placement of a well facility at Site 1. The facility at Site 1 would not be located within the area of play, and construction would not substantially damage this recreational resource.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.12-2, Appropriate Siting of Proposed Facilities: Locate WSIP project facilities on park and recreation properties in consultation with park planning staff to minimize the direct loss of recreation and play space and to minimize inconvenience to park and recreation users.	N	This PEIR mitigation measure was implemented during conceptual design of the GSR Project. Several proposed well facility sites would be located at or near a recreational facility, including construction in athletic fields at local schools and at the Lake Merced Golf Club. As part of Project implementation, construction schedules would be altered to avoid construction during the school year to minimize loss of play space. The Project Description commits the SFPUC to repairing or replacing the existing baseball backstop at Site 3; temporarily removing and then replacing the baseball backstop at Site 4; returning the athletic fields to pre-project conditions; and financially compensating the Lake Merced Golf Club for the loss of a restroom. The site to be located at the Lake Merced Golf Club would not be within the area of play, and construction would not substantially damage this recreational resource. Implementation of mitigation measures to control construction noise and construction dust would reduce the impact on the quality of the recreational experience at the golf club and athletic fields to a less-than-significant level.
Agriculture		
Measure 4.13-1a, Supplemental Noticing and Soil Stockpiling: For the San Joaquin Pipeline projects (San Joaquin System and Rehabilitation of Existing San Joaquin Pipeline), stockpile and replace topsoil in mapped areas of Prime and Unique Farmland and Farmland of Statewide Importance that would be temporarily disturbed by pipeline construction, unless other actions are required under specific agreements with individual landowners.	N	The GSR Project would not be located in the San Joaquin Region.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.13-1b, Avoidance or Soil Stockpiling: Minimize any potential impacts on agricultural lands in the Sunol Valley by avoiding these resources wherever possible. Where this is not possible, stockpile, replace, and hydroseed topsoil to prevent erosion, unless other actions are required as a result of contracts affecting use of the property or under specific agreements with individual landowners.	N	The GSR Project would not be located in the Sunol Valley.
Measure 4.13-2, Siting Facilities to Avoid Prime Farmland: Avoid areas identified as Prime Farmland, Unique Farmland, or Farmland of Statewide Importance. If avoidance is not feasible, adopt a permanent set-aside for an equivalent acreage of similarly valued farmland in the area.	N	No impacts to agricultural resources would occur from GSR Project construction.
Hazards		
Measure 4.14-1a, Site Health and Safety Plan: For all projects where the site assessment indicates the potential to encounter hazardous materials, prepare a site health and safety plan identifying the chemicals present, potential health and safety hazards, monitoring, soil-handling methods, appropriate personnel protective equipment, and emergency response procedures.	Y	See Mitigation Measure M-HZ-2b (Health and Safety Plan) and M-HZ-2c (Hazardous Materials Management Plan). The project-level mitigation measures combines the requirements for a site health and safety plan and materials disposal plan required in PEIR Measures 4.14-1a and 4.14-1b.
Measure 4.14-1b, Materials Disposal Plan: For all projects where the site assessment indicates the potential to encounter hazardous materials in the soil, prepare a materials disposal plan that specifies the disposal method and approved disposal site for the soil.	Y	See Mitigation Measure M-HZ-2b (Health and Safety Plan) and Mitigation Measure M-HZ-2c (Hazardous Materials Management Plan). The project-level mitigation measures combines the requirements for a site health and safety plan and materials disposal plan required in PEIR Measures 4.14-1a and 4.14-1b.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.14-1c, Coordination with Property Owners and Regulatory Agencies: Based on regulatory agency file reviews, assess the potential to encounter unacceptable levels of hazardous materials at known environmental cases, for construction activities to cause groundwater plume migration or interfere with ongoing remediations at known environmental cases, and for increased water levels in reservoirs or lakes to inundate known environmental cases. Modify construction or remediation activities.	Y	The project-level analysis evaluated the potential for encountering contaminated soils and groundwater during GSR Project construction. Mitigation Measure M-HZ-2a (Preconstruction Hazardous Materials Assessment) is included to require a preconstruction hazardous materials assessment within three months of construction to identify new hazardous materials sites or substantial changes in the extent of contamination at known groundwater contamination sites that could affect subsurface conditions at proposed well facility sites. The Project-specific analysis concludes that construction activities would not cause groundwater plume migration or interfere with remediation activities during construction. The Project does not include construction activities that would cause increase water levels at reservoirs or lakes. Operation of the Project may cause increased water levels at Lake Merced, as described in Impact BR-7. This significant impact would be mitigated to less-than-significant levels through implementation of Mitigation Measure M-BR-7 (Lake Level Management for Water Levels).
Measure 4.14-2, Health Risk Screening and Airborne Asbestos Monitoring Plan: For tunneling projects where soil or rock may contain naturally occurring asbestos, conduct a health risk screening assessment to identify acceptable levels of asbestos in tunnel emissions. Prepare an airborne asbestos monitoring plan for approval by the BAAQMD.	N	The GSR Project would not include tunneling and would not disturb a rock unit or soil that contains naturally occurring asbestos. See GSR Section 5.15.1 (Setting) in Section 5.15, Geology and Soils.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.14-5, Hazardous Building Materials Surveys and Abatement: For all WSIP projects involving demolition or renovation of existing facilities, perform a hazardous building materials survey for each structure prior to demolition or renovation activities. If any friable asbestos-containing materials, lead-containing materials, or hazardous components of building materials are identified, implement adequate abatement practices prior to demolition or renovation.	N	The SFPUC would be required to assess and abate hazardous building materials from demolition of the restroom at Site 1 and well with structure at Site 14 in accordance with applicable laws and regulations. Therefore, since the impact was determined to be less than significant, implementation of PEIR Mitigation Measure 4.14-5 is not required.
Energy		
Measure 4.15-2, Incorporation of Energy Efficiency Measures: Consistent with the Energy Action Plan II priorities for reducing energy usage, ensure that energy-efficient equipment is used in all WSIP projects. Prepare a repair and maintenance plan for each facility to minimize power use. Evaluate the potential for use of renewable energy resources.	N	See Impact ME-2. The collective energy demand of the GSR Project well facilities, the Partner Agencies' well facilities, and the SFPUC regional water system would remain at approximately 61 million kW, and the proposed Project would not cause an increase in energy use. Therefore, no mitigation is needed. However, the SFPUC would incorporate all applicable energy efficiency measures into the project design. Projects with building components will attempt to maximize energy efficiency by exceeding Title 24 minimum requirements by at least 20 percent and meet or exceed LEED Silver certification.
Collective Impacts		
Measure 4.16-1a, Construction Coordination at Irvington Portal: If construction schedules of multiple WSIP projects occurring at and near Irvington Portal coincide or overlap, the SFPUC will coordinate with construction contractor(s) and neighbors to minimize disturbance of residents in the adjacent neighborhood to the extent practicable. Such coordination will need to balance the duration of construction with the magnitude of construction-related impacts on the same sensitive receptors.	N	The GSR Project would not be located at the Irvington Portal.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Collective Impacts (cont.)		
Measure 4.16-4a, Bioregional Habitat Restoration Measures: Address the following bioregional effects and implement conservation principles when implementing habitat compensation mitigation required for individual WSIP facility projects: compound impacts on functional units of habitat as WSIP projects simplify vegetation structure and increase "edge" (the boundary between two different habitats); increased habitat impacts due to the spread of weedy, non-native plant species; genetic diversity impacts on small populations; impacts on wildlife movement due to habitat fragmentation; suppression of natural disturbance regimes; and reduced population recovery opportunities from stochastic events.	N	The GSR Project's contribution to cumulative effects on biological resources would be mitigated with project-specific mitigation measures and therefore would not require implementation of bioregional habitat restoration measures.
Measure 4.16-4b, Coordination of Construction Staging and Access: Coordinate construction contractor(s) to minimize surface disturbance when construction schedules for WSIP projects affecting the same areas overlap.	N	The only overlap in construction staging areas would occur at Site 8. At Site 8, the construction area for the Peninsula Pipelines Seismic Upgrade Project would overlap with the construction area for the well facility at Site 8. No significant biological impacts are projected to occur at Site 8, and therefore there is no need for mitigation no coordinate staging and access areas.
Measure 4.16-6a, SFPUC WSIP Projects Construction Coordinator: Identify a qualified construction coordinator to coordinate project-specific traffic control plans; develop a public information campaign to inform the public of construction activities, detour routes, and alternate routes; and work with local and regional agencies to pursue additional traffic mitigation measures and incorporate such measures into the project-specific traffic control plans.	Y	See Mitigation Measure M-C-TR-1 (Coordinate Traffic Control Plan with other SFPUC Construction Projects). The PEIR measure for a SFPUC WSIP project construction coordinator is incorporated into the Project-level measure for cumulative impacts.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Collective Impacts (cont.)		
Measure 4.16-6b, Combined San Joaquin Traffic Control Plan: Develop a San Joaquin Traffic Control Plan that coordinates the project-specific traffic control plans and identifies additional measures (consistent with the standards of San Joaquin County, Stanislaus County, and Caltrans) to minimize the combined impacts of multiple WSIP project construction traffic on I-580, Chrisman Road, and Vernalis Road.		The GSR Project would not be located in San Joaquin County.
Measure 4.16-6c, Combined Sunol Valley Traffic Control Plan: Develop a Sunol Valley Traffic Control Plan that coordinates the project-specific traffic control plans and identifies additional measures (consistent with the standards of Alameda County and Caltrans) to minimize the impacts of construction traffic on Calaveras Road and I-680.	N	The GSR Project would not be located in Sunol Valley.
Measure 4.16-7a, Dust and Exhaust Control Measures for All WSIP Projects: Require implementation of Air Quality Measures 4.9-1a thru 4.9-1d for all WSIP projects to address collective construction-related air quality impacts.	Y	Specified air quality measures are required under project-level Mitigation Measures M-AQ-2a (BAAQMD Basic Construction Measures) and M-AQ-2b (NOx Reduction during Construction of Alternate Sites). The project-level measures are consistent with the PEIR measure.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Collective Impacts (cont.)		
Measure 4.16-7b, Health Risk Screening or Use of Soot Filters for All Projects in the San Joaquin and Sunol Valley Regions: Require Measure 4.9-2a for all WSIP projects in the San Joaquin and Sunol Valley Regions to address collective DPM impacts. When this requirement is applied to the New Irvington Tunnel project, it will be applied to both the Sunol Valley and Fremont tunnel portals, taking into account truck traffic from other WSIP projects in the vicinity of both portals.	N	The GSR Project would not be located in either the San Joaquin or Sunol Valley region.
Measure 4.16-7c, Vacate SFPUC Land Managers' Residences for All Projects in the Sunol Valley Region: Require Measure 4.9-2b for all WSIP projects in the Sunol Valley Region to address collective DPM impacts.	N	The GSR Project would not be located in Sunol Valley.
Measure 4.16-8a, Limiting Hourly Truck Volumes and Restricting Truck Operations on Haul Routes for Multiple WSIP Projects: Apply Measures 4.10-2a and 4.10-2b to total haul and delivery truck volumes attributable to all WSIP projects on any particular haul truck route (including haul routes in the Tesla Portal, Irvington Portal, and Lower Crystal Springs Dam vicinities as well as haul routes in the San Francisco Region) to address collective truck-related noise impacts.	N	See Impact NO-4. The project-level analysis determined that noise levels from truck trips would fall below the daytime speech interference thresholds and within the range of existing baseline noise levels along roadways serving the sites. Therefore, PEIR Mitigation Measure 4.16-8a was determined not to be applicable to the GSR Project.

TABLE D-3
WSIP PEIR Mitigation Measure Consistency

PEIR Mitigation Measure(s)	Applicable to Proposed Project (Y/N)?	Discussion
Measure 4.16-8b, Vacate Land Manager's Residence for All Projects in Sunol Valley Region: To address collective noise impacts, vacate Land Manager's residence adjacent to Alameda East Portal during construction truck operations associated with all WSIP projects in this region if collective daytime truck volumes exceed the 70-dBA speech interference criterion or nighttime truck volumes exceed the 50-dBA sleep interference criterion.	N	The GSR Project would not be located in Sunol Valley.
Cumulative Effects		
Measure 4.17-6, SFPUC WSIP Projects Construction Coordinator – Other Agencies: The SFPUC WSIP construction coordinator designated in accordance with Measure 4.16-6a will also consider the effects of any traffic generated by SFPUC maintenance activities and other SFPUC projects; and coordinate with Caltrans, other county agencies, and local jurisdictions regarding construction of other private and public development projects so as to minimize traffic impacts on local access roads.	Y	See Mitigation Measure M-C-TR-1 (Coordinate Traffic Control Plan with other SFPUC Construction Projects). The project-level measure is consistent with the PEIR measure and requires construction coordination with other agencies and other WSIP projects.
Measure 4.17-8, Coordination of Truck Traffic on Local Streets: The SFPUC WSIP construction coordinator designated in Measure 4.17-6 will also be responsible for coordinating truck traffic generated on these same streets by SFPUC maintenance activities and other SFPUC projects so that SFPUC-related truck noise increases are maintained at or below threshold levels specified in Measures 4.10-2a and 4.10-2b to the extent feasible.	Y	See Mitigation Measure M-C-TR-1 (Coordinate Traffic Control Plan with other SFPUC Construction Projects). The project-level measure is consistent with the PEIR measure and requires construction coordination with other agencies and other WSIP projects, however, the Mitigation Measure is intended to reduce congestion and safety concerns, not reduce significant noise impacts from construction truck traffic

Introduction

Illingworth & Rodkin, Inc., under subcontract to GHD, has prepared this air quality emissions analysis and health risk assessment that evaluates the impacts associated with the San Francisco Public Utilities Commission's (SFPUC's) Regional Groundwater Storage and Recovery Project (the project), which includes installation and operation of up to 16 new groundwater production well facilities within the South Westside Groundwater Basin, consideration of three alternate sites for the well facilities, and a pump station upgrade. This analysis was prepared following the scope of work submitted to San Francisco Planning Department's Environmental Planning Division (EP), dated October 28, 2011, and included in this report as *Appendix 1*. The scope of work was developed in consideration of the Bay Area Air Quality Management District (BAAQMD) CEQA Air Quality Guidelines[1]. These guidelines include thresholds for construction emissions and community risk.

Based on a writ mandated by the Alameda Superior Court, these thresholds have currently been set aside and the BAAQMD has to cease dissemination of them until the BAAQMD complies with CEQA for the adoption of the thresholds. As a result, the BAAQMD is no longer recommending the 2011 thresholds be used to measure a project's significant air quality impacts. Instead, the BAAQMD suggests that lead agencies use the 1999 CEQA thresholds to make determinations regarding the significance of an individual project's air quality impacts. However, the Planning Department has determined that Appendix D of the 2011 BAAQMD CEQA Air Quality Guidelines, in combination with BAAQMD's Revised Draft Options and Justification Report, provide substantial evidence to support the BAAQMD recommended thresholds and, therefore, has determined they are appropriate for use in CEQA analyses[2].

In accordance with the 2011 BAAQMD CEQA Air Quality Guidelines and thresholds, this air quality technical report addresses the significance of:

- Construction-period emissions; and
- Construction-period health risk, including cumulative risk.

Operational emissions from the Project are considered to be negligible, since there would be no direct emissions expected from the facilities and maintenance or worker travel would be infrequent. Worker maintenance trips would produce very small emissions. Indirect emissions from use of electricity for the pumps would decrease, because existing Partner Agency wells would pump less over the long-term, and new wells would use green electricity from the SFPUC Power Enterprise.

Project Description

The proposed project would increase water supply reliability during dry years or in emergencies, by increasing water storage in the Westside Groundwater Basin during wet and normal years for subsequent recapture during dry years. The proposed Project is located in San Mateo County and is sponsored by the SFPUC in coordination with its partner agencies, which include the cities of Daly City and San Bruno, and the California Water Company (Cal Water) in its South San Francisco service area (collectively referred to as Partner Agencies).

The SFPUC currently supplies surface water to the Partner Agencies from its regional water system. The Partner Agencies supply potable water to their retail customers through a combination of groundwater from the South Westside Groundwater Basin and purchase of SFPUC surface water. The proposed project would provide supplemental SFPUC surface water to the Partner Agencies during normal and wet years. During these

[1] BAAQMD. *CEQA Air Quality Guidelines*. May, 2011.

[2] BAAQMD. *Revised Draft Options and Justification Report California Environmental Quality Act Thresholds of Significance*. October, 2009.

years, the Partner Agencies would reduce their groundwater pumping by a comparable amount to increase the amount of groundwater in storage through natural (in-lieu) recharge. During normal and wet years, the volume of groundwater in the South Westside Groundwater Basin would increase due to natural recharge and reduced groundwater pumping by the Partner Agencies. During dry years, the Partner Agencies and the SFPUC would pump the stored groundwater using 16 new well facilities, as needed to supplement other supplies. This new dry-year water supply would be blended with water from the SFPUC regional water system, and would thereby increase the available water supply to all regional water system customers.

The proposed project consists of the construction and operation of up to 16 new well facilities within the South Westside Groundwater Basin and an upgrade to the existing Westlake Pump Station. The EIR includes the evaluation of three additional well facilities (19 wells in total) in the instance where one of the 16 preferred well facilities cannot be successfully constructed or operated. The calculation of emissions is presented for both the preferred 16 well sites and an "alternate scenario" of 16 well sites that include the three alternate sites.

Each well facility would contain a well pump station, distribution piping, and utility connections. Most well facilities would also have disinfection units designed to eliminate bacteria in the groundwater using chlorine and ammonia. At certain sites, additional treatment (i.e., pH adjustment, fluoridation, and/or iron/manganese removal) has been incorporated into the design of the facility to meet both regulatory and water quality targets in the finished water for all agencies.

Site-specific well facility characteristics for the 19 potential well facility sites are listed in *Appendix 7*. These characteristics include the proposed well facility (i.e., building) type, pump type and pumping capacity, water distribution system connection point and alternate connection point (if any), groundwater disinfection location, and the method that would be used to achieve water quality goals. Water treatment may occur at the well site or at off-site treatment areas. For the purpose of calculating emissions, the connection point is assumed to be the one which would require a longer pipeline for connection, as this would represent the maximum emissions.

Groundwater from Sites 2, 3, and 4 would be conveyed to the Westlake Pump Station for treatment prior to addition to the Daly City distribution system. Sites 5, 6, and 7 include two treatment options: Consolidated Treatment at Site 6 and On-site Treatment. Under the consolidated treatment option, groundwater from Sites 5 and 7 would be conveyed to Site 6 for treatment before addition to the SFPUC regional water system. The consolidated treatment option requires pipelines to convey water from Sites 5 and 7 to Site 6. Under the on-site treatment option, groundwater would be treated at each of the sites, and water treated on-site would be added directly to the SFPUC regional water system. For the purpose of calculating emissions, only the On-site Treatment option is evaluated for criteria air pollutants, because construction of three separate buildings with treatment systems would generate more emissions than the Consolidated Treatment at Site 6 option which only has one building at Site 6. However, both options are evaluated for health risk impacts.

The proposed well facilities have been designed and sited so that wells are close to treatment systems and close to existing distribution systems (the SFPUC regional water system and the local distribution systems of the Partner Agencies), resulting in a more energy efficient system. Of the 16 well facility sites evaluated for the Project, four well facilities would connect to Daly City's distribution system; three to San Bruno's distribution system; two to Cal Water's distribution system; and seven to the SFPUC regional water system.

Well facility types would be either a:

- Well with a fenced enclosure which would include fencing, the wellhead, pump, piping and associated electrical controls; or
- Well with a building which would house the wellhead, pump, piping, treatment system, and associated electrical controls.

Where a building is proposed, the building size would vary between 20 feet x 35 feet to 23 feet by 103 feet. For the purpose of calculating emissions, all buildings were assumed to be the largest building size.

Each site would require underground piping to connect the new well to the local water distribution system or to the SFPUC regional water system, or to connect the well to a neighboring facility for treatment. Underground piping would connect well facilities to the local storm drain system and/or the sanitary sewer system to allow discharge of overboard well water, chloraminated water, or filter backwash. The total pipe length required for all 19 well facility sites, including either of the distribution system connections (whichever one is longer), would be approximately 19,000 feet of 6-inch and 8-inch pipe.

Project Construction Schedule

The SFPUC proposes to construct the project starting in June 2014, with completion targeted for May 2016 (an additional three months is provided in the event of a schedule delay, however construction would occur over 21 months as indicated in Table 1). Construction would occur in clusters of four well facilities, plus an alternate site, grouped together as shown in Table 1. Within each construction cluster, well construction would occur during the first month, followed by approximately three months of construction at the sites without a building or approximately 16 months of construction for sites with a building.

Site 17 (Alternate)	July 2014	August 2014	August 2014	November 2015

Project Construction Methods

Wells

To install a production well on a site with no existing test well, the site would first be cleared of vegetation, if present, which would be temporarily stockpiled on-site. Then an area would be graded (as needed) and covered with gravel base rock, to create a level pad for supporting the drill rig and other equipment. A 30-inch steel conductor casing would be installed to a depth of 50 feet and cemented in place. A minimum 22-inch diameter production borehole would be drilled to a depth of approximately 500 to 750 feet, the approximate depth of the aquifer that is proposed for production. Drilling and other drilling related activities (e.g., equipment and material delivery to support drilling) would extend for about a week both during the day and night. The well casing, consisting of a 12-inch diameter stainless steel well casing and well screen would be installed in the borehole. A 2-inch diameter steel pipe would be welded to the well casing and installed to a depth of approximately 350 to 400 feet. Finally, an impervious seal consisting of sand/cement grout would be placed in the well annular space above the filter pack.

Various well pumping tests would be performed after final well development. These tests would include: (a) pumping for durations of two hours each at different discharge rates ("step-drawdown test"); and (b) continuous pumping for 12 to 48 hours at the final design capacity of the well ("constant-discharge aquifer test").

After construction is complete, well sites would be restored to their general pre-construction conditions, and all disturbed areas would be hydroseeded and receive erosion control measures as necessary.

Well Facilities

Construction of facilities at the well sites may require additional site clearing and grubbing beyond that conducted for the well drilling. Most of the proposed facility sites are located within developed urban areas, many on existing rights-of-way where large SFPUC transmission pipes have previously been installed. Accordingly, large portions of many of the sites have already been disturbed. Site excavation and grading would be minor, with grading to a maximum depth of five feet for the building foundation (if the well facility is intended to have a building) and utilities underneath the building. After the foundation and utilities connections are constructed, the remainder of the building would be constructed and the well pump and other equipment installed, as needed.

Water Distribution and Utility Pipeline Installation

New pipelines would be installed below ground using standard open-trench construction methods. Open-trench construction involves the following steps:

1. vegetation removal and grading or pavement cutting depending on the location,
2. trench excavation and shoring to stabilize the sides of the trench if necessary,
3. pipeline installation,
4. trench backfilling and compacting, and
5. surface restoration.

<u>Project Operation</u>

The SFPUC and Partner Agencies would operate 16 new well facilities with an annual average pumping capacity of 7.2 million gallons per day (equivalent to 8,100 acre-feet per year) to provide a supplemental dry-year water supply. During dry-year conditions, Partner Agencies would also pump from their own existing wells up to annual average rates consistent with the pumping limitations expressed in the project's Operating Agreement. During wet or normal years, weekly or monthly exercising of the production wells for one- to four-hour periods would be required to ensure that the facilities remain operational. Operators may fine-tune the exercise schedule according to the characteristics of individual wells.

The well facilities would be powered by electricity. All well facilities would have provisions for a drive-up portable generator connection, so that in the event of a power failure the well pumps could continue to run in a dry year or be used as a temporary alternate water supply (in a normal or wet year). The portable diesel generators would be trailer-mounted models with built-in sound reduction and spill containment features. SFPUC or the Partner Agencies would utilize existing generators and would not acquire new generators for this project.

Operation and maintenance activities would result in less than one vehicle trip to each site per day during a dry year and less than one vehicle trip per week during a wet or normal year. As a result, vehicle emissions associated with operation of the project would be negligible.

Project Setting

Appendix 2 includes aerial maps that show each facility site (including the planned construction footprint) and sensitive receptors located within 1,000 feet of each facility site. Also shown on those maps are cumulative sources of toxic air contaminants (TACs). These sources include freeways, highways, high volume roadways, and stationary sources listed by BAAQMD. Sensitive receptor locations include residential dwellings, schools, daycare facilities, senior care facilities, and medical facilities, as defined in the BAAQMD CEQA Air Quality Guidelines.

Project Significance Thresholds

Table 2 summarizes the air quality thresholds of significance used in this analysis. These thresholds are based on an evaluation by EP of thresholds identified by BAAQMD in May 2011[3].

TABLE 2
Air Quality Significance Thresholds

Pollutant	**Construction Thresholds**	**Operational Thresholds**	
	Average Daily Emissions (lbs./day)	**Average Daily Emissions (lbs./day)**	**Annual Average Emissions (tons/year)**
Criteria Air Pollutants			
ROG	54	54	10
NO_x	54	54	10
PM_{10}	82	82	15
$PM_{2.5}$	54	54	10
CO	Not Applicable	9.0 ppm (8-hour average) or 20.0 ppm (1-hour average)	
Fugitive Dust	Construction Dust Ordinance or other Best Management Practices	Not Applicable	
Health Risks and Hazards for New Sources			
Excess Cancer Risk	10 per one million	10 per one million	
Chronic or Acute Hazard Index	1.0	1.0	
Incremental annual average $PM_{2.5}$	0.3 µg/m^3	0.3 µg/m^3	

[3] BAAQMD. *California Environmental Quality Act Guidelines*. May, 2011.

TABLE 2
Air Quality Significance Thresholds

Pollutant	**Construction Thresholds**	**Operational Thresholds**	
	Average Daily Emissions (lbs./day)	**Average Daily Emissions (lbs./day)**	**Annual Average Emissions (tons/year)**
Health Risks and Hazards for Sensitive Receptors (Cumulative from all sources within 1,000 foot zone of influence) and Cumulative Thresholds for New Sources			
Excess Cancer Risk	100 per one million		
Chronic Hazard Index	10.0		
Annual Average $PM_{2.5}$	0.8 µg/m^3		

Note: ROG = reactive organic gases, NOx = nitrogen oxides, PM_{10} = course particulate matter or particulates with an aerodynamic diameter of 10 micrometers (µm) or less, and $PM_{2.5}$ = fine particulate matter or particulates with an aerodynamic diameter of 2.5µm or less.

Project Emissions Modeling

On-site construction-period air pollutants were modeled using the latest version of the California Emissions Estimator Model, CalEEMod (Version 2011.1.1). The mobile emissions during construction, which include haul truck trips, vendor or delivery truck trips, and worker trips, were computed using the EMFAC2011 model developed by the California Air Resources Board (CARB). Both models also provide greenhouse gas emissions that were utilized as part of the project environmental impact analysis. The on-site modeling was based on the construction equipment inventories and schedule provided by SFPUC. A production well would be installed at each site, except for the Westlake Pump Station and Sites 2, 5, 6, 8, 10, and 13 where test wells currently exist. Either a well facility building or a fenced enclosure would be constructed at each site. In addition, pipelines would be installed to connect the well facilities to the existing distribution system. Interior upgrades at the Westlake Pump Station were not modeled because there would be very little use of diesel-powered equipment, so health risk impacts would be negligible. Emissions associated with each component of the construction activities were computed as follows:

- Well Drilling/Well Construction anticipated to last 30 working days
- Construction of Well Facility Building anticipated to last 240 working days
- Construction of Fenced Enclosure (for sites that would not have buildings) anticipated to last 40 working days
- Construction of pipeline anticipated to be constructed at a rate of 120 feet per day

For sites with well facility buildings, the largest building construction scenario was assumed and applied to each site on which a building is proposed, because this phase of construction would have the highest emissions. For Sites 5, 6 and 7, a well facility building was assumed at each site, because this configuration would have the highest emissions. Pipeline construction was based on an assumption that 120 feet of pipeline could be constructed in an average work day, because the majority of the pipeline is in soil where minimal obstructions are anticipated.

Model input assumptions are based on the type and quantity of equipment, projected average daily usage (in hours) and size (in terms of horsepower). Where horsepower was unknown, the CalEEMod default value for that type of equipment was assumed. CalEEMod only computes annual emissions in tons per year or maximum daily emissions in pounds per day. Since some of the construction phases would have relatively low emissions, predicting annual emissions was found to be problematic, because CalEEMod only predicts emission in tons with accuracy to one significant decimal point. For $PM_{2.5}$ emissions, which are used for the health risk analysis, this would introduce a large error in the predicted emissions. To avoid this type of error, average daily emissions for an entire construction phase (e.g., Construction of Well Facility Building) were predicted by inputting the usage of each piece of construction equipment with average hours per day based on the entire construction duration. For example, a grader would be operated for approximately 4 hours on one day during the Site Preparation sub-phase of Production Well Installation, but was modeled as operating for 0.1 hours per Phase Day (4 hours divided by 30 days) to account for the average amount of time it would be operated over the course of the entire 30-day phase. As a result, average daily construction period emissions from the off-road equipment operating at each site were computed in terms of pounds per day.

Construction equipment assumptions in CalEEMod were adjusted to account for the CARB overestimation of emissions, because the model is based on older load factor assumptions. CARB adjusted construction fleet emissions by reducing the load factors used in their OFFROAD model by 33 percent. Since CalEEMod is also based on the same OFFROAD model, the load factors in the model for this project were also reduced by 33 percent.

Mobile-source emissions were computed using the CARB EMFAC2011 model that computes emissions from on-road vehicles. The emissions from haul truck tips were assumed to be all heavy heavy-duty trucks. Vendor and delivery truck trips were computed assuming a mix of 50 percent heavy-duty trucks and 50 percent medium-duty trucks. Worker trips were assumed to be 50 percent light-duty automobiles and 50 percent light-duty trucks. Vehicle trips were assumed to be the default trip lengths used in CalEEMod, which are 12.4 miles for worker trips, 7.3 miles for vendor truck trips and 20 miles for heavy-duty and heavy heavy-duty truck trips. Emissions for 10 minutes of idling were applied to each haul truck roundtrip, which would include 5 minutes for each trip.

Table 3 shows criteria air pollutant emissions associated with construction of each site. It is possible that alternate sites (Sites 17, 18 and 19) may need to be constructed. As an “alternate scenario”, it is assumed that Site 1 through 19 plus the Westlake Pump Station modification would be developed, because these sites would represent the construction of all 19 possible sites. This would result in the maximum emissions.

The emissions are reported as total emissions for each site in pounds and average daily emissions are computed for the entire project construction period, assumed to be 420 days. Construction days were calculated based on 20 construction days over 21 months. Average daily emissions are compared against the daily criteria air pollutant emission significance thresholds and found to be below the significance thresholds, both for Sites 1-16 and the alternate scenario. However, NO_x emissions would exceed the significance thresholds under the Alternate Scenario where all 19 sites plus the Westlake Pump Station modification are constructed. Detailed emissions computations and assumptions along with CalEEMod modeling output are contained in *Appendix 3*.

Note that the computed emissions do not include fugitive dust, which is treated separately under the BAAQMD CEQA Air Quality Guidelines. Application of Best Management Practices for minimizing dust emissions that are identified in the BAAQMD CEQA Air Quality Guidelines would minimize those impacts to a less than significant level.

Mitigation of Project Construction NO_x Emissions for Construction of Alternate Sites

If one to three wells at Sites 1-16 are constructed but found to be unusable for any reason, and one to three wells are therefore constructed at alternate sites, the SFPUC shall reduce modeled NO_x emissions by 20% at the alternate sites. To meet this performance standard, the SFPUC shall develop and implement a plan demonstrating that the off-road equipment (i.e., equipment rated at more than 50 horsepower that is owned or leased by the contractor or subcontractors) to be used in constructing the wells and facilities at the alternate sites would achieve a fleet-wide average 20-percent NO_x reduction compared to the most recent CARB fleet average.

Acceptable options for reducing emissions include the use of late model engines (i.e., meeting U.S. EPA Tier 3 standards or later), low emission diesel products, alternative fuels that have lower NO_x emissions, engine retrofit technology, after-treatment products, add-on devices, and/or other options that may become available.

Construction NOx emissions for construction of all sites were recomputed assuming that all on-site off-road construction equipment used in constructing the wells and facilities at the alternate sites would have emissions that are 20 percent lower than the current fleet-wide average assumed in the CalEEMod model. With this mitigation measure, construction of all 19 sites plus the Westlake Pump Station modifications would result in daily NO_x emissions of 53.7 pounds per day on average over the 420-day construction period, which is below the threshold of 54 pounds per day.

TABLE 3
Estimated Criteria Air Pollutant Construction Emissions (in pounds)

Health Risk Analysis

The construction activities will require the use of heavy-duty diesel vehicles and equipment, which emit diesel particulate matter (DPM) as $PM_{2.5}$, which is a toxic air contaminant (TAC) that is identified by CARB as causing cancer. In addition, the organic gas components of diesel exhaust can pose non-cancer hazards. In order to address health risk impacts, emissions from construction activities are input to a dispersion model that computes DPM/$PM_{2.5}$ and organic compound concentrations at receptors. The exposures are computed based on receptor type (i.e., residential infant or adult, school child or daycare child) and the corresponding risks are based on the toxicity of the TAC and the sensitivity of the receptor (e.g., infant, child or adult). The corresponding cancer risk and non-cancer hazards are computed and the receptor with the highest impact is considered the maximum exposed individual (MEI).

BAAQMD Regulation 2, Rule 5 sets cancer risk limits for new and modified sources of TACs at the MEI at 10 chances per million. In addition to cancer risk, some TACs pose non-carcinogenic chronic and acute health hazards. Acute and chronic non-cancer health hazards are expressed in terms of a hazard index, or HI, which is a ratio of the TAC concentration to a reference exposure level (REL), a level below which no adverse health effects are expected, even for sensitive individuals.[4] If the HI is 1.0 or greater, which means that the TAC concentration equals or exceeds the REL, then the exposure is considered significant. In addition, particulate matter, primarily associated with construction equipment and mobile sources (vehicular emissions) is strongly associated with mortality, respiratory diseases, and impairment of lung development in children, and other endpoints such as hospitalization for cardiopulmonary disease. The U.S. Environmental Protection Agency (EPA) has proposed a Significant Impact Level (SIL) for $PM_{2.5}$. For developed urban areas, including much of San Francisco, the EPA has proposed a SIL of between 0.3 $\mu g/m^3$ to 0.8 $\mu g/m^3$. The SIL represents the level of incremental $PM_{2.5}$ emissions that represents a significant contribution to regional non-attainment.[5] The lower range of the EPA-recommended SIL of 0.3 $\mu g/m^3$ is an appropriate threshold for determining the significance of a source's $PM_{2.5}$ impact.

Potential health risks and hazards from project construction activities on existing sensitive receptors are assessed within a 1,000-foot zone of influence through (1) prediction of emissions from project activities; (2) dispersion modeling to identify exposure and (3) computing the resulting risks and hazards based on the type of receptor exposed.

Project Emissions of TACs

Emissions of TACs were based on the project emissions modeling described above using the CalEEMod and EMFAC2011 models. Since all construction equipment was assumed to be diesel powered, all $PM_{2.5}$ emissions computed using CalEEMod were assumed to be DPM. The diesel $PM_{2.5}$ vehicle emissions produced by EMFAC2011 were assumed to represent DPM from on-road mobile sources associated with construction.

For each construction phase, the CalEEMod provided daily emissions of $PM_{2.5}$ exhaust emissions (assumed to be DPM) and emissions of ROG from the off-road construction equipment in pounds per day. These emissions were converted into grams per second per square meter ($g/sec/m^2$) for input into a dispersion model. The construction area was based on the size of the construction footprint for each construction phase (i.e., well construction, building or fenced enclosure construction and pipeline construction). Truck traffic emissions generated by the project were converted into grams per second per cubic meter ($g/sec/m^3$) for on-site truck travel and g/sec for trucks while traveling off-site for input into the dispersion model. Worker traffic was assumed to have a negligible affect on health risk due to the relatively low volume of traffic generated and the small amount of emissions when compared with daily construction equipment and truck activity. Much of the worker travel emissions occur beyond 1,000 feet from the facility sites. So those emissions from worker vehicle trips were not included in the health risk assessment.

Two sets of emissions were computed: (1) emissions based on average daily activity through the course of each construction component used to compute cancer risk and annual $PM_{2.5}$ concentrations and (2) a maximum daily scenario that uses the maximum daily emissions computed by CalEEMod when considering each sub-phase of construction (i.e., site preparation, building construction, or trenching for pipeline work) to compute acute non-cancer health risk. Therefore, the highest hourly concentration modeled using the maximum daily emission scenario was calculated.

For non-cancer health effects of DPM the California Office of Health Hazard Assessment (OEHHA) has established DPM concentration levels for evaluating chronic health effects; however, concentration levels for acute (short-term) health effects have not been identified for DPM as a whole. Thus, in order to evaluate potential acute health effects from exposure to diesel exhaust, the individual chemicals that make up the total organic gas (TOG) portion of diesel exhaust were evaluated for acute health effects. A speciation profile of individual chemicals in the TOG from off-road diesel equipment exhaust provided by the BAQMD was used to identify the compounds for evaluation of acute health effects. It was assumed that the ROG emissions computed using CalEEMod are functionally equivalent to TOG emissions, and, therefore, the ROG emissions from construction activities were used to calculate the emissions and concentrations for the individual chemicals with acute non-cancer health effects. The speciation profiles and the applicable toxicity values, based on acute exposures, are shown in Table 4.

Air Dispersion Modeling

As part of the health risk assessment, the U.S. EPA ISCST3 dispersion model was used to predict concentrations of DPM and ROG at existing residences and other sensitive receptors surrounding the facility sites. The ISCST3 dispersion model is a BAAQMD-recommended model for use in refined modeling analysis of CEQA projects[6]. The model calculates pollutant concentrations at receptors located in areas of flat or complex terrain from a variety of emission source types including point, area, volume and line sources. The model was run using regulatory default dispersion options and urban dispersion coefficients due to the urban nature of the project area.

[6] BAAQMD. *Recommended Methods for Screening and Modeling Local Risks and Hazards*. Version 2.0, May, 2011.

Annual modeled concentrations based on average daily emissions rates were used to compute cancer risk. Modeled worst-hour concentrations were used to compute acute hazards resulting from speciated TAC components of diesel exhaust with acute risks using BAAQMD speciation factors[7].
Emissions from on-site construction equipment were modeled as a series of area sources in the areas associated with construction activities. An emission release height of 6 meters was used for each area source. DPM emissions from truck traffic on-site were included in the on-site area sources and the off-site trucks traveling on the roadways near the facility sites were modeled as line sources (a series of volume sources along a path). Line sources for off-site truck travel were used to simulate the expected travel routes along local roadways within the 1,000-foot zone of influence from the construction sites.

Modeled receptors were placed at sensitive receptors anticipated to have the greatest impacts that are within 1,000 feet of the modeled construction site. For assessing impacts, the receptor with the highest impacts from construction activities within 1,000 feet would be identified as the maximum exposed individual (MEI). All receptors were assumed to be at ground-level with a breathing height of 1.5 meters. Since there is variation in the terrain elevations at some of the facility sites and surrounding areas, terrain elevations were used with the model. Elevations for project emission sources and sensitive receptor locations were obtained from USGS Digital Elevation Model (DEM) data for the project area. Receptor locations and the depiction of the project emission sources are shown in the figures provided in *Appendix 2*.

BAAQMD collects and records meteorological data at a number of locations throughout the Bay Area. In the vicinity of the facility sites, there are two BAAQMD meteorological monitoring stations for which the BAAQMD has processed the hourly data for use with the ISCST3 model. Based on the locations of the facility sites, BAAQMD recommended that meteorological data collected at the District's Fort Funston station be used for sites 1 through 7 and data collected at San Francisco International Airport and processed by the District be used for the remaining sites[8]. BAAQMD provided the ISCST3 formatted data for both sites.

Emissions, computed for the project using CalEEMod as described above, were modeled as occurring between 7 am - 7 pm. For each site, these emissions would occur in 2014 and 2015. Annual concentrations were predicted for each year along with the maximum hourly concentration. For most sites, worst day emissions occurred during well installation. Well Facility Building construction had the highest emissions for those sites that did not include well construction.

The health risk associated with 19 facility sites was analyzed to capture potential health risks, even though only 16 facility sites would be constructed. Health risk was estimated by calculating risk at groups of geographically close sites. Some facility sites are separated sufficiently that they would not have additive effects with other sites. However, effects from some facility sites overlap with the effects from other sites ; therefore, those facility sites that had overlapping 1,000-foot zone of influences were grouped and modeled together, with an MEI for each group of modeled sites identified. Nine modeling groups were evaluated as follows, with Group 3 modeled under two different scenarios:

Group 1: Facility Site 1
Group 2: Facility Sites 2, 3 and 4
Group 3: Facility Sites 5, 6 and 7 (On-site Treatment)
Group 3: Facility Sites 5, 6, and 7 (Consolidated Treatment at Site 6)
Group 4: Facility Site 8 and Site 17 (Alternate)
Group 5: Facility Sites 9 and 10 and Site 18 (Alternate)
Group 6: Facility Sites 11 and 12 and Site 19 (Alternate)

[8] Based on email from James Cordova (BAAQMD) to Bill Popenuck (Illingworth & Rodkin, Inc.), dated April 16, 2012.

Group 7: Facility Site 13
Group 8: Facility Sites 14 and 15
Group 9: Facility Site 16
Note: Westlake Pump Station Upgrade was not included in health risk analysis, as noted under project Emissions Modeling above.

Excess Lifetime Cancer Risk and $PM_{2.5}$ Prediction

The dispersion modeling provided the annual $PM_{2.5}$ concentration predicted at each receptor. As discussed previously, $PM_{2.5}$ emissions from the project are conservatively assumed to be all DPM. The annual DPM concentrations are used to compute increased cancer risk caused by the project.

Increased cancer risks at each of the sites were calculated using the modeled annual average concentrations and using the most recent methods recommended by BAAQMD[9] and the California Office of Environmental Health Hazard Assessment (OEHHA)[10]. The factors used to compute cancer risk are highly dependent on modeled concentrations, exposure period or duration, and the type of receptor. The exposure level is determined by the modeled concentration; however, it has to be averaged over a representative exposure period. The averaging period is dependent on many factors, but primarily the type of sensitive receptor that would reside at a site. OEHHA has developed exposure assumptions for typical types of sensitive receptors. These include nearly continuous exposures for residences.

It should be noted that the cancer risk calculations for residential exposures reflect use of BAAQMD's most recent cancer risk calculation method, adopted in January 2010[11]. The cancer risk calculations were based on applying the BAAQMD recommended age sensitivity factors to TAC concentrations. Age sensitivity factors reflect the greater sensitivity of infants and children to cancer causing TACs. This analysis assumed that residential and daycare receptors represented infant exposures and applied a sensitivity factor of 10 to the cancer risk calculations. Where exposures were assumed to be school children, an age sensitivity factor of 3 was applied. An age sensitivity factor of 1 was applied to adult exposures. This analysis, therefore, presents the most conservative cancer risk for various types of exposures.

The cancer risk calculations incorporate breathing rates of 581 liters per kilogram day (L/kg-day) for infants and children and 302 L/kg-day for adults. Since the modeling was conducted assuming emissions occurred 365 days per year, a default OEHHA exposure period of 350 days per year was used. For school and daycare child exposure, they were assumed to be exposed to the construction emissions for 10 hours per day out of the 12 hours of daily construction emissions.

MEIs were identified for each geographic group of sites and are shown on Figures 1 through 10 in *Appendix 2*. The MEI for Group 3 is shown for the On-site Treatment configuration, because it represents a higher health risk than Group 3 with Consolidated Treatment at Site 6. The MEI for the group with the highest risk is the MEI for the project as a whole.

Table 5 summarizes the excess lifetime cancer risk and $PM_{2.5}$ concentrations for each group of sites at the MEIs. Cancer risk computations for each facility site, along with the assumptions used, are presented in *Appendix 4.* The figures contained in *Appendix 2* show model receptors and sources. Results were compared to the excess lifetime cancer risk threshold of 10 per million (evaluated as 10.0 per million) and an annual $PM_{2.5}$ concentration thresholds of 0.3 $\mu g/m^3$.

[11] BAAQMD. *Air Toxics NSR Program Health Risk Screening Analysis (HRSA) Guidelines.* January, 2010.

Non-Cancer Hazard Index

Table 5 also includes the predicted chronic or acute hazards at the MEIs for each geographic group of sites, expressed as the hazard index (HI). Potential non-cancer health effects due to chronic exposure to DPM were estimated using the modeled $PM_{2.5}$ concentration and the chronic inhalation REL for DPM of 5 µg/m^3. There is no REL for acute exposures associated with DPM. Therefore, speciated total organic gas components of diesel exhaust that have acute toxicity values assigned were used to evaluate hazards due to acute exposures. For this assessment, ROG emissions were considered to be equivalent to total organic gas emissions from construction activities. Emissions were modeled using CalEEMOD, which provides ROG emissions. Modeled worst-hour concentrations were used to compute acute hazards resulting from speciated TAC components of DPM with acute risks using BAAQMD speciation factors[12]. BAAQMD risk management policy does not recommend including acrolein in health risk assessments due to the lack of reliable emissions data[13]. EP recommends that acrolein be included for truck traffic, but not off-road construction emissions. Since the project would generate very little hourly truck traffic during construction, the effects of acrolein were not evaluated. Table 4 includes the speciation profiles and acute toxicity values for organic DPM compounds.

Discussion of Excess Cancer Risks, Hazard Indices, and $PM_{2.5}$ Concentrations

The excess cancer risk, hazard index for acute or chronic exposures (whichever is highest) and the highest $PM_{2.5}$ concentrations for each of the geographic groups of sites are shown in Table 5. The results shown in Table 5 apply to the MEI for each group. Results that exceed the applicable thresholds are highlighted in Table 5.

As indicated in Table 5, the excess cancer risk at the MEI for each geographic group caused by construction of the project would range from 1.05 to 10.74. The highest value would be 10.74, which exceeds the BAAQMD threshold of 10 in a million, at Group 3 for Sites 5, 6, and 7 for the On-site Treatment option. Because construction of Group 3 with On-site Treatment would have the highest risk, the MEI for Group 3 would also be the MEI for the project as a whole.

The Hazard Index, which evaluates non-cancer health risks, would range from 0.11 to 0.72, which is less than the BAAMQD project impact threshold of 1.00. The annual $PM_{2.5}$ concentrations would range from 0.01 to 0.07 µg/m^{3,} which would be less than the BAAMQD project impact threshold of 0.3 µg/m^3.

TABLE 5
Project and Cumulative Cancer Risks, Non-Cancer Hazard Indices and $PM_{2.5}$ Concentrations

[c] The acute or chronic hazard index is reported, whichever is higher.

Mitigation of Project Construction Health Risks for Group 3 with On-site Treatment

During the construction of Site 5 (On-site Treatment), the SFPUC shall utilize off-road equipment (more than 50 horsepower) with late model engines meeting U.S. EPA Tier 4 (Interim), or utilize a combination of Tier 2 or Tier 3 engines with add-on devices that consist of level 3 diesel particulate filters.

Construction emissions for Group 3, which includes Site 5 (On-site Treatment), Site 6 (On-site Treatment), and Site 7 (On-site Treatment), were recomputed in CalEEMod assuming that all on-site off-road construction equipment larger than 50 horsepower for construction of the well facility building would have diesel engines that meet the minimum mitigation requirements. This would reduce $PM_{2.5}$ emissions by greater than 50 percent. As a result, excess cancer risks were computed to be less than 5.39 per million. The resulting cancer risks with mitigation would be below the significance thresholds.

Cumulative Health Risk Analysis

Potential health risks and hazards were assessed from TAC sources that are located within 1,000 feet of the MEIs for each geographic group of sites. Note that the MEI refers to the receptor that has the greatest impact with respect to health risks caused only by the project. Cumulative sources were then identified for each group of facility sites and the impact of those sources upon the MEI for each group was evaluated. For those sources that were more than 1,000 feet from the MEI for each group, the contribution to the cumulative impact was considered to be negligible (i.e., the sources beyond the 1,000-feet radius had a negligible contribution to the MEI cancer risk, non-cancer hazards or $PM_{2.5}$ concentrations). For each group of sites, cumulative health risks were predicted at the MEI for that group.

These cumulative health risks are presented in Table 5. The cumulative risk analysis included the aggregate effects of past, present and foreseeable TAC sources within 1,000 feet of the MEI for the group; these sources included the project, highways, local roads (with average daily volume above 10,000 vehicles), and stationary sources identified using BAAQMD's database. Cumulative TAC source data are included in Appendix 5.

Roadways

Busy roadways are a source of TAC emissions that could affect sensitive receptors near the facility site. The BAAQMD provides screening tables that indicate predicted community risk impacts that roadways pose[14]. These tables were used to develop screening levels of cancer risk and $PM_{2.5}$ concentrations. Note that the screening tables published by BAAQMD indicate that non-cancer chronic and acute hazards from traffic would be well below the BAAQMD thresholds. BAAQMD reports the chronic and acute Hazard Index for local roadways as less than 0.02. The traffic level on each roadway was estimated and rounded upward to the traffic volumes analyzed by the BAAQMD screening tables. Traffic volumes were estimated by assuming the peak-hour traffic volumes reported in the traffic section (1st Administrative Draft EIR, Transportation and Circulation Section Table 5.6-3) was about 8 to 10 percent of the average daily traffic volume. The distance between the roadway and the MEI for each geographic group was measured and the screening levels cancer risk and $PM_{2.5}$ levels were identified in the BAAQMD screening tables.

BAAQMD provides a Highway Screening Analysis Google Earth Map tool to identify estimated risk and hazard impacts from highways throughout the Bay Area. Cumulative risk, hazard and $PM_{2.5}$ impacts at various distances from the highway are estimated for different segments of the highways. The tool uses the average annual daily traffic (AADT) count, fleet mix and other modeling parameters specific to that segment of the highway. Impacts from Interstate 280 and State Route 82 were assessed using this tool.

---

14 BAAQMD. Roadway Analysis Tables can be accessed from BAAQMD's website at: *http://www.baaqmd.gov/Divisions/Planning-and-Research/CEQA-GUIDELINES/Tools-and-Methodology.aspx*. Note that these tables are used to determine whether additional refined analyses are necessary.

Stationary Sources

The risk, hazard and $PM_{2.5}$ impacts from stationary sources were assessed using the BAAQMD Stationary Source Screening Analysis Google Earth Map tool. This tool was used to identify sources within 1,000 feet of the MEI locations. BAAQMD provided screening risk data for each of the identified sources. BAAQMD also provided distances multipliers to adjust the risk and $PM_{2.5}$ concentrations of gasoline station and diesel engine sources from the screening distance of 50 feet to the actual measured distance. In the case where screening risk data were not available, a source health risk screening assessment (HRSA) was requested from BAAQMD through the Stationary Source Information Request process.

CalTrain Rail Line at Group 9 (Site 16)

Trains using the CalTrain rail line are a source of DPM emissions. The CalTrain rail line near Group 9 was modeled to assess cancer risk, hazards and $PM_{2.5}$ concentrations at the group MEI location affected by Group 9. The rail line within the 1,000 ft buffer area of Site 16 was modeled using ISCST2 with hourly historical meteorological data from San Francisco International Airport.

Annual DPM/$PM_{2.5}$ emissions were computed based on the current schedule that includes 62 CalTrain passenger trains and 4 freight trains. Travel speed was assumed at 30 mph. CalTrain is planning to electrify the line, so DPM emissions may not occur in the future, however no definitive date for implementation has been established. DPM emissions from CalTrain were assumed to occur through the year 2025. For acute impacts, maximum short-term emissions were calculated assuming there would be a maximum of 3 trains (2 Caltrain and 1 freight train) during a one-hour period passing the MEI location.

Based on this modeling, the child exposure cancer risk was 4.5 per million at a DPM/$PM_{2.5}$ concentration of 0.03 $\mu g/m^3$. The chronic DPM HI was 0.005. The maximum 1-hour volatile organic compound concentration was 1.09 $\mu g/m^3$. TAC concentrations with acute health effects were calculated using the U.S. EPA Speciation Profile 4674 for Medium Duty Trucks. The acute total Hazard Index is 0.01 from rail traffic.

Discussion of Cumulative Excess Cancer Risks, Hazard Indices, and $PM_{2.5}$ Concentrations

Table 5 shows the cumulative risk, hazard indices and annual $PM_{2.5}$ concentrations for construction at each group of sites. Results that exceed the applicable thresholds are highlighted in Table 5.

The cumulative excess cancer risk at the MEIs for the groups would range from 4.12 to 29.09. The project MEI would be at Group 3 (Sites 5, 6, 7 with On-site Treatment). The cumulative excess cancer risk to the project MEI would be 28.93 in one million, which is below the cumulative significance threshold of 100 in one million.

The cumulative non-cancer Hazard Index at the MEIs for the groups would range from 0.16 to 0.76. The cumulative Hazard Index for the project MEI would be at Group 2 (Sites 2, 3, and 4) and is predicted to be 0.76, which is below the cumulative significance threshold of 10.0.

The cumulative annual $PM_{2.5}$ concentration at the MEIs for the groups would range from 0.05 $\mu g/m^3$ to 14.53 $\mu g/m^3$. The highest value for the cumulative annual $PM_{2.5}$ concentration occurs at Group 7 (Site 13) and is due primarily to a stationary source in South San Francisco, Bimbo Bakery. Much of this concentration appears to be caused by fugitive emissions of flour from the flour holding tanks, reported only as PM or total particulate matter and assumed to be all $PM_{2.5}$. The cumulative $PM_{2.5}$ concentration from construction at Group 7 would exceed the BAAQMD threshold of 0.8 $\mu g/m^3$, however the project contribution to this cumulative impact is only 0.01 $\mu g/m^3$. The cumulative annual $PM_{2.5}$ concentration for the project MEI at Group 3 is predicted to be 0.33 $\mu g/m^3$, which is below the cumulative significance threshold of 0.8 $\mu g/m^3$.

Health Risk Uncertainties

The resulting health risks reported are based on a series of assumptions related to predicted emissions, concentrations, exposures, and chemical toxicity. The assumptions used in the analysis are generally conservative and meant to provide upper-bound estimates of risk. Emissions from the project are based on the best available estimates of project activity and emissions factors from models recommended by BAAQMD. The uncertainty of the emissions is unknown. Dispersion modeling to predict resulting concentrations was conducted using a model recommended by BAAQMD that used meteorological data recommended by the District's meteorologist. The exposure periods are assumed to be almost continuous for the type of receptors modeled (i.e., the receptors will be present almost continuously during the period that activity occurs). In addition, the most sensitive receptors that could be present were assumed. For example, an infant was assumed to be continuously present at all residential receptors. Infants were considered to be ten times more susceptible to carcinogenic TACs. In general, the methods used in this risk assessment are meant to be conservative, so that the real risks from the source would be lower than the risks predicted in this assessment.

GSR Air Quality Scope of Work, dated June 24, 2011 and Revised October 28, 2011

ILLINGWORTH & RODKIN, INC.
Acoustics • Air Quality

Memo

To: Kristine Gaspar, *Winzler & Kelly*

Date: June 24, 2011, Revised October 28, 2011

From: James A. Reyff

Subject: Regional Groundwater Storage and Recovery (GSR) Project EIR Air Quality Analysis

---

As you are aware, Illingworth & Rodkin, Inc. (I&R) prepared a draft air quality analysis of GSR Project environmental impacts. That air quality analysis was conducted in 2009 and used the URBEMIS2007 model to conservatively analyze air pollutant emissions from construction of the project. Operational emissions were considered to be negligible, since there were no emissions expected from the facilities and maintenance or worker travel would be minor.

Since that analysis was conducted, the Bay Area Air Quality Management District (BAAQMD) adopted new CEQA Air Quality Guidelines. These guidelines include adopted thresholds for construction emissions and community risk. GSR emissions are difficult to compare against thresholds, because construction activities at each well facility site are quite small, but there are 20 potential construction sites. The construction schedule (see attached) indicates that construction of all sites may overlap to some extent.

A new CEQA air quality issue that has come up is community health risk associated with construction activities. In May 2010, BAAQMD made construction screening tables available that indicate the distances from construction activities to where health risk for $PM_{2.5}$ levels would be at less-than-significant levels. These tables are quite conservative and indicate that minimal setbacks would be around 300 feet. District staff admittedly believes these are quite conservative and expect to issue more refined guidance in 2011.

In response to the new BAAQMD CEQA Air Quality Guidelines, the San Francisco Planning Department's Environmental Planning (EP) division has developed new guidance for reviewing environmental documents. Where there are substantial or significant air quality issues, the guidance requires an air quality technical report. As a result, there are several air quality issues that need to be addressed for this project:

1. Significance of construction period emissions as compared to the new BAAQMD CEQA thresholds;
2. Prediction of construction period health risk impacts; and
3. Preparation of an Air Quality Technical Report per EP guidelines.

Below is the proposed scope of work to prepare a Focused Air Quality Technical Report for the GSR Project. This scope addresses the three items listed above.

Project Description

The purpose of the proposed Project is to further the use of the South Westside Groundwater Basin as an underground storage reservoir by storing water in the basin during wet periods for subsequent recapture during dry periods. The San Francisco Public Utilities Commission (SFPUC) proposes to provide surface water to the cities of Daly City and San Bruno, and the California Water Company (Cal Water) in its South San Francisco service area (collectively designated as Partner Agencies) to be used by these agencies in lieu of pumping groundwater during normal and wet rainfall years. As part of the Project, SFPUC would install new groundwater well facilities, which would be operated by SFPUC and the Partner Agencies for pumping groundwater during dry years as part of the regional water supply.

The proposed Project consists of installation and operation of up to 16 new groundwater production well facilities within the South Westside Groundwater Basin. Nineteen well facility sites are currently being evaluated; however, a maximum of 16 well facilities would be developed and operated as part of the Project. In addition, an existing pump station site may be upgraded.

The new project sites are located in San Mateo County overlying the South Westside Groundwater Basin. Four well facilities would connect to Daly City's distribution system; three well facilities would connect to San Bruno's distribution system; three well facilities would connect to Cal Water's distribution system; and nine well facilities would connect to the SFPUC distribution system. Most of the proposed project sites are located within developed urban areas, many on existing rights-of-way where large SFPUC transmission pipes have previously been installed. Accordingly, large portions of many of the sites have already been disturbed.

Each groundwater well facility site would contain a pump or a well facility to house above-ground pumps, and pipeline and utility trenches to connect the site to water mains, sanitary sewer, storm drains, and the electrical grid. In some cases monitoring wells and geotechnical borings may be installed. In addition, the Westlake Pump Station may require upgrades.

The SFPUC proposes to construct the proposed Project starting in February 2013 through approximately November 2015. The well facility sites would be constructed in groups of four and phased during this time period. Not all construction activities include traditional air-emitting activities such as ground disturbance and running of heavy equipment. Following is a list of the activities and estimated duration associated with construction of a single well facility and its associated features.

- Monitoring well (if needed): approximately 3 weeks each.
- Geotechnical boring (as needed): 1 day each.
- Production well: 45 days each.
- Well station building: 14 months total for each building
    - Clearing and grubbing and other site preparation activity: 1 month
    - Foundation and utility connections: 2 months
    - Building and equipment: 9 months
    - Start-up and testing: 2 months

- Well facilities at Sites 2, 3, and 4: These facilities would be constructed only during the summer months (when school is not in session).
- Pipelines: 300 to 600 feet per week (approximately one to two blocks per week).
- 16 months total.

All construction activities would occur during the daytime hours, from 7 AM to 7 PM, Monday through Friday except for construction of wells, which would require nighttime construction during drilling and other drilling-related activities (for seven consecutive days/nights) and a pump test (for one continuous 48-hour period) at each site.

Focused Air Quality Technical Report

The Air Quality Technical Report would focus on construction period impacts and explain why operational impacts are not quantified (the only operational emissions identified are, at maximum, from one maintenance vehicle visit per day and eight supply deliveries per month to a well site with full treatment).

The Focused Air Quality Technical Report for the project will include the following sections:

Project Description

A brief project description would be prepared, focusing on those elements of the GSR Project that relate to air quality. Since the project includes 20 project sites, a reference to the detailed project description would be included to keep the report to a reasonable size. The attached figures will be used in the Report.

Project Setting

Construction activities that would generate emissions of TACs will be described for each kind of project site. Maps showing the construction sites and the surrounding sensitive receptors would be shown. A table listing the distance from the nearest sensitive receptor to the construction area boundary will be included. In addition, other sources of TAC emissions identified using BAAQMD's stationary source screening tool would be identified on these maps.

Impact of Criteria Air Pollutants

Construction period criteria air pollutants would be modeled using the latest version of the CalEEMod . Construction equipment assumptions in the model would be adjusted to account for the California Air Resources Board (CARB) overestimation of emissions. These adjustments would be verified with City staff or CARB. Model input in terms of equipment quantity, daily usage, size, and number of days used at the site will be developed in consultation with SFPUC. Average daily construction period emissions would be computed. Average daily emissions would be compared against the BAAQMD significance thresholds. Mitigation measures to reduce fugitive dust, and if necessary, exhaust emissions would be identified. Emissions of on-site (construction site) diesel exhaust fine particulate matter emissions developed in this task would be used in the health risk assessment tasks described below.

Single-Source Health Risk Construction Analysis

Where sensitive receptors are located within 1,000 feet of a construction site, the potential for health effects in terms of community risk would be addressed. I&R would conduct a health risk assessment that would model emissions from each of the construction project sites (i.e., construction of a well or pump facility, including chemical treatment and filtration). The pipeline construction associated with these sites would be included. Even though pipeline construction is expected to have very small impacts due to the short duration, the pipeline construction within 1,000 feet of the well facility construction sites would be included.

This modeling would be conducted by computing construction period emissions of toxic air contaminants (TACs) and $PM_{2.5}$ and using dispersion models to predict the received concentrations. The health risks associated with the received concentrations would be assessed by applying BAAQMD risk calculation methods that include age-sensitivity factors. Health risk would be predicted per BAAQMD Risk Management policy. Details of this analysis include:

- Construction Emissions would be computed using the CalEEMod model as described above. If construction equipment is known or SFPUC commits to certain construction equipment fleet emissions requirements, then CARB's OFFROAD2007 and EMFAC2007 model would be used. As described above, construction equipment activity levels would be determined using the CalEEMod model, unless specific information is provided by SFPUC. All $PM_{2.5}$ exhaust emissions from on-site off-road and on-road equipment will be considered as diesel particulate matter. The latest off-road equipment load factors recommended by CARB would be applied to the CalEEMod modeling.

- EPA's ISCST3 model would be used to model emissions from the construction activities. The first approach would be to identify appropriate hourly meteorological data that could be used in this task. This would be done by consulting with BAAQMD's meteorologist in consultation with City staff. Otherwise, screening meteorological conditions would be used to model a worst-hour concentration. The worst-hour concentration would be converted to an annual concentration to address cancer, non-cancer chronic health risk impacts and annual $PM_{2.5}$ concentrations. Modeled worst-hour concentrations would be used to compute acute hazards resulting from acrolein and all other speciated TAC components of DPM with acute risks using BAAQMD speciation factors[1]. Annual concentrations would be adjusted from worst-hour concentrations by applying a 0.1 persistence factor. Screening meteorological conditions would be based on the meteorological conditions used by the SCREEN3 model[2]. Receptors would be placed at sensitive receptors anticipated to have the greatest impacts that are within 1,000 feet from the modeled construction site. For assessing impacts, the receptor with the highest impacts from construction activities within 1,000 feet would be identified. This analysis would also take into account the situations where some receptors would be within 1,000 feet of more than one construction site. A draft receptor grid will be provided to EP for review prior to modeling and revised per EP comments.

- Health risks and $PM_{2.5}$ concentrations would be predicted based on BAAQMD guidance for sensitive receptor exposures. We would confirm the exposure assumptions and speciation factors for emissions with the City EP Division and BAAQMD to ensure risks are not under or over predicted. The analysis would incorporate the appropriate breathing rates (for adults and children), hours of operation and the number of days per year that emissions would occur.

<u>Cumulative Health Risks</u>

---

[1] Speciation factors would be based on a 3/30/2011 email from Virginia Lau (BAAQMD). The City EP Division and/or BAAQMD would be consulted to identify the acute reference exposure levels.

[2] The SCREEN3 meteorological data is a set of 54 discrete combinations of wind speed, wind direction and atmospheric stability.

Screening tables and screening analysis tools provided by BAAQMD along with the database on stationary sources would be used to identify community risk impacts from other nearby sources. The impact from project construction combined with published impacts from roadways or stationary sources within 1,000 feet of each project site would be compared against the BAAQMD thresholds. At this point, modeling of cumulative sources that are not part of the project is not proposed. It is assumed, at this time, that cumulative impacts from non-project sources would not contribute to a significant cumulative health risk. If cumulative risk would exceed the BAAQMD thresholds, then additional refined modeling, which is not included in this scope of work, may be necessary.

For each site, a table would be developed for the maximally exposed individual (MEI), based on exposure to the project construction sites. This table would report the cancer risk, chronic and acute non-cancer risk and $PM_{2.5}$ concentration associated with the project (including the combination of multiple project sites that are within 1,000 feet). This would be the maximum project impact and compared to the BAAQMD community risk thresholds for a single source (e.g., cancer risk of 10 in one million).

In addition, the table would list the impacts from other sources using BAAQMD screening tables for roadways and BAAQMD's stationary source database. The impacts from roadways would be looked up in the screening tables based on the receptor distance from the roadway. Impacts from stationary sources would be based on a search using BAAQMD's Google Earth Stationary Source tool to initially identify the nearby sources. For each site that has identified stationary sources within 1,000 feet, a request would be made to BAAQMD to provide the screening level risk and $PM_{2.5}$ data that would be used as screening level. BAAQMD distance adjustment factors for any diesel engines would be applied. These data would be entered into the table and combined with the project impacts to assess cumulative risk. The risk from each source would be added and the total would be compared against BAAQMD's community risk thresholds for cumulative sources (e.g., cancer risk of 100 in one million).

<u>Appendices</u>

The model print outs, speciation tables, emission factors, and this scope of work will be included in the appendices. In addition, correspondence with any agency, such as BAAQMD or CARB, which was used in developing the technical report, will be included.

1. Revise equipment type, except "On Highway Trucks," as appropriate for this project. Provide hp if known.
2. For "On Highway Trucks" (which includes vendors, haul trucks,& deliveries) the "quantity of equipment" should be reported as round trip truck trips.
3. Working days are counted as 20 days within a calendar month.

* Typically we use an average of 60 - 120 ft/day pipeline construction, depending on conditions. Majority of the pipeline in this project is in soil where we would anticipate minimal obstructions, so we can assume a higher production rate.

** Assume pump, tanks, and other equipment installed during building construction, while fork lift and crane are avaialble. The 40 days includes testing

*** Needed for pipeline work in the street.

Emision rates from CARB Idling Emission Rates for EMFAC2011-HD Vehicle Categories, Feb. 8, 2012

Idle time per vehicle round trip assumet to be = 10 minutes

[a] Idle emissions from employee vehicles assumed to be negligible

[b] Idle emissions from Vendor/Equipment vehicles assumed to be same as for MHDT vehicle category

[c] Idle emissions from Heavy Duty Trucks and Heavy-Heavy Duty trucks assumed to be same as for HHDT vehicle category

Entrained Roadway Dust (PM10)
gm/mi

Vehicle	PM10	PM2.5
All	0.116	0.029

EPA AP-42 Section 13.2.1

$E = k(sL)^{0.91} \times (W)^{1.02}$ EPA AP-42 Section 13

Where:

k (PM2.5) = 0.25

k (PM10) = 1.00

sL = 0.035 g/m2 for major & colle

W = 2.4 tons

a. Pipelines listed in the table are illustrated on site plans for each site – Figures 3-12 through Figure 3-39.

b. The water connection pipeline for Sites 2, 3, and 4 includes the length of pipeline needed to connect to the existing Daly City pipeline for conveyance to the Westlake Pump Station.

c. Water connection pipelines for Site 5 (Consolidated Treatment at Site 6) and Site 7 (Consolidated Treatment at Site 6) include the pipeline length necessary to deliver water to Site 6 for treatment.

Maximum Daily Emissions

CalEEMod Version: CalEEMod.2011.1.1

Date: 4/19/2012

GSR - Pipeline Per Day Construction

San Mateo County, Summer

1.0 Project Characteristics

1.1 Land Usage

Land Uses	Size	Metric
General Heavy Industry	1	1000sqft

1.2 Other Project Characteristics

Urbanization Urban

Climate Zone 5

Wind Speed (m/s) 2.2

Precipitation Freq (Days) 70

Utility Company

1.3 User Entered Comments

Project Characteristics -

Land Use - Small Area for pipeline

Construction Phase - These are per-day estimates of activity that would construct 120-linear feet of pipeline

Off-road Equipment - Project-specific equipment & LF adjustment (-33%)

Off-road Equipment - Max. Worst Day equipment activity based on one day of pipline construction

Adjusted load factors by -33%

Trips and VMT - Worker trips computed seperately using EMFAC2011

Cancer Risk Calculation Method

Cancer Risk (per million) = CPF x Inhalation Dose x 1.0E6

Where: CPF = Cancer potency factor (mg/kg-day)$^{-1}$

Inhalation Dose = C_{air} x DBR x A x EF x ED x 10^{-6} / AT

Where: C_{air} = concentration in air ($\mu g/m^3$)
DBR = daily breathing rate (L/kg body weight-day)
A = Inhalation absorption factor
EF = Exposure frequency (days/year)
ED = Exposure duration (years)
AT = Averaging time period over which exposure is averaged.
10^{-6} = Conversion factor

Exposure Parameter	Units	Exposure Type: Residential Child	Residential Adult	School Child	Day Care Child
Breathing Rate (DBR)	(L/kg-day)	581	302	581	581
Exposure period					
Daily	(hours/day)	24	24	10	10
Annual (EF)	(days/year)	350	350	180	245
Exposure Duration (ED)	(years)	2	2	2	2
Exposure Period	(years)	70	70	70	70
Averaging Time (AT)	(days)	25,550	25,550	25,550	25,550
Age Adjustment Factor (ASF)	-	10	1	3	10

Site Construction Activities

Daily (hours/day) = 12
Weekly (days/week) = 5
Annual (days/year) = varies by site

Modeling Time Periods

Days used in Model (days/year) = 365
Hours used in Model (hours/day) = 12 (7am - 7 pm)

DPM Health Risk Factors

DPM Cancer Potency Factor (mg/kg-day)-1 = 1.10E+00
DPM Reference Exposure Level (ug/m^3) = 5

GSR - Construction Impacts

San Mateo County
PM2.5 Concentrations and Cancer Risks Generated from Surface Streets

How to use the screening tables:

- Distance is from the edge of the nearest travel lane of a street to the facility or development
- When two or more streets are within the influence area, sum the contribution from each street

$PM_{2.5}$ CONCENTRATIONS (UG/M^3)

NORTH-SOUTH DIRECTIONAL ROADWAY

Annual Average Daily Traffic	Distance East or West of Surface Street - PM2.5 Concentration (ug/m^3)

- Screening tables based on meteorological data collected from San Mateo Sewage Treatment Plant in 2005.
- The maximum acute and chronic hazard index for the distances and AADT shown in the table will be less than 0.02.
- Cancer risk were estimated based on exposure from 2014 through 2084. PM2.5 concentrations were based on emissions in 2014.

Bay Area Air Quality Management District

Risk & Hazard Stationary Source Inquiry Form

This form is required when users request stationary source data from BAAQMD. This form is to be used with the BAAQMD's Google Earth stationary source screening tables.

For guidance on conducting a risk & hazard screening, including for roadways & freeways, refer to the District's Risk & Hazard Analysis flow chart.

Also see the District's Recommended Methods for Screening and Modeling Local Risks and Hazards document.

Table A: Requestor Contact Information	
Contact Name:	James A. Reyff
Affiliation:	Illingworth & Rodkin, Inc.
Phone:	707-766-7700
Email:	jreyff@illingworthrodkin.com
Date of Request	4/9/2012
Project Name:	Regional Groundwater Storage and
Address:	various
City:	
County:	
Type (residential, commercial, mixed use, industrial, etc.):	Public Works - Pump Stations
Project size (# of units, or building square feet):	<3,000 sf
Comments:	

For Air District assistance, the following steps must be completed:

Complete all the contact and project information requested in Table A. Incomplete forms will not be processed. Please include a project site map.

Download and install the free program Google Earth, http://www.google.com/earth/download/ge/, and then download the county specific Google Earth stationary source application files from the District's website, http://www.baaqmd.gov/Divisions/Planning-and-Research/CEQA-GUIDELINES/Tools-and-Methodology.aspx. The small points on the map represent stationary sources permitted by the District (Map A on right). These permitted sources include diesel back-up generators, gas stations, dry cleaners, boilers, printers, auto spray booths, etc. Click on a point to view the source's Information Table, including the name, location, and preliminary estimated cancer risk, hazard index, and PM2.5 concentration.

Find the project site in Google Earth by inputting the site's address in the Google Earth search box.

Using the Google Earth ruler function, measure the distance in feet between the project's fenceline and the stationary source's fenceline for all the sources that are within 1,000 feet of the project's fenceline. Verify that the location of the source on the map matches with the source's address in the Information Table, by using the Google Earth address search box to confirm that the source is within 1,000 feet of the project. Please report any mapping errors to the District (District contact information in Step 9).

If the stationary source is within 1,000 feet of the project's fenceline and the stationary source's information table does not list the cancer risk, hazard index, and PM2.5 concentration, and instead says to "Contact District Staff", list the stationary source information in Table B Section 1 below.

Note that a small percentage of the stationary sources have Health Risk Screening Assessment (HRSA) data INSTEAD of screening level data. These sources will be noted by an asterisk next to the Plant Name (Map B on right). If HRSA values are presented, these values have already been modeled and cannot be adjusted further.

Email this completed form to District staff (Step 9). District staff will provide the most recent risk, hazard, and PM2.5 data that are available for the source(s). If this information or data are not available, source emissions data will be provided. Staff will respond to inquiries within three weeks.

Note that a public records request received for the same stationary source information will cancel the processing of your SSIF request.

Submit forms, maps, and questions to Alison Kirk at 415-749-5169, or akirk@baaqmd.gov.

Footnotes:

1. These Cancer Risk, Hazard Index, and PM2.5 columns represent the rows in the Google Earth Plant Information Table that say "Contact District Staff" (Map A above). BAAQMD will return this form to you with this screening level information entered in thes
2. Each plant may have multiple permits and sources.
3. Fuel codes: 98 = diesel, 189 = Natural Gas.
4. Permitted sources include diesel back-up generators, gas stations, dry cleaners, boilers, printers, auto spray booths, etc.
5. If a Health Risk Screening Assessment (HRSA) was completed for the source, the application number will be listed here.
6. The date that the HRSA was completed.
7. Engineer who completed the HRSA. For District purposes only.
8. All HRSA completed before 1/5/2010 need to be multiplied by an age sensitivity factor of 1.7.
9. The HRSA "Chronic Health" number represents the Hazard Index.
10. Further information about common sources:
    a. Sources that only include diesel internal combustion engines can be adjusted using the BAAQMD's Diesel Multiplier worksheet.
    b. The risk from natural gas boilers used for space heating when <25 MM BTU/hr would have an estimated cancer risk of one in a million or less, and a chronic hazard index of 0.003 or less. To be conservative, requestor should assume the cancer risk is 1 i
    c. BAAQMD Reg 11 Rule 16 required that all co-residential (sharing a wall, floor, ceiling or is in the same building as a residential unit) dry cleaners cease use of perc on July 1, 2010. Therefore, there is no cancer risk, hazard or PM2.5 concentrations from co-residential dry cleaning businesses in the BAAQMD.
    d. Non co-residential dry cleaners must phase out use of perc by Jan. 1, 2023. Therefore, the risk from these dry cleaners does not need to be factored in over a 70-year period, but instead should reflect the number of years perc use will continue after t
    e. Gas stations can be adjusted using BAAQMD's Gas Station Distance Mulitplier worksheet.
    f. Unless otherwise noted, exempt sources are considered insignificant. See BAAQMD Reg 2 Rule 1 for a list of exempt sources.
    g. This spray booth is considered to be insignificant.

Date of Request	4/9/2012
Project Name:	Regional Groundwater Storage and
Address:	various
City:	
County:	
Type (residential, commercial, mixed use, industrial, etc.):	Public Works - Pump Stations
Project size (# of units, or building square feet):	<3,000 sf
Comments:	

For Air District assistance, the following steps must be completed:
Complete all the contact and project information requested in Table A. Incomplete forms will not be processed. Please include a project site map.
Download and install the free program Google Earth, http://www.google.com/earth/download/ge/, and then download the county specific Google Earth stationary source application files from the District's website, http://www.baaqmd.gov/Divisions/Planning-and-Research/CEQA-GUIDELINES/Tools-and-Methodology.aspx. The small points on the map represent stationary sources permitted by the District (Map A on right). These permitted sources include diesel back-up generators, gas stations, dry cleaners, boilers, printers, auto spray booths, etc. Click on a point to view the source's Information Table, including the name, location, and preliminary estimated cancer risk, hazard index, and PM2.5 concentration.
Find the project site in Google Earth by inputting the site's address in the Google Earth search box.
Using the Google Earth ruler function, measure the distance in feet between the project's fenceline and the stationary source's fenceline for all the sources that are within 1,000 feet of the project's fenceline. Verify that the location of the source on the map matches with the source's address in the Information Table, by using the Google Earth address search box to confirm that the source is within 1,000 feet of the project. Please report any mapping errors to the District (District contact information in Step 9).
If the stationary source is within 1,000 feet of the project's fenceline and the stationary source's information table does not list the cancer risk, hazard index, and PM2.5 concentration, and instead says to "Contact District Staff", list the stationary source information in Table B Section 1 below.
Note that a small percentage of the stationary sources have Health Risk Screening Assessment (HRSA) data INSTEAD of screening level data. These sources will be noted by an asterisk next to the Plant Name (Map B on right). If HRSA values are presented, these values have already been modeled and cannot be adjusted further.
Email this completed form to District staff (Step 9). District staff will provide the most recent risk, hazard, and PM2.5 data that are available for the source(s). If this information or data are not available, source emissions data will be provided. Staff will respond to inquiries within three weeks.
Note that a public records request received for the same stationary source information will cancel the processing of your SSIF request.
Submit forms, maps, and questions to Alison Kirk at 415-749-5169, or akirk@baaqmd.gov.

Footnotes:
1. These Cancer Risk, Hazard Index, and PM2.5 columns represent the rows in the Google Earth Plant Information Table that say "Contact District Staff" (Map A above). BAAQMD will return this form to you with this screening level information entered in thes
2. Each plant may have multiple permits and sources.
3. Fuel codes: 98 = diesel, 189 = Natural Gas.
4. Permitted sources include diesel back-up generators, gas stations, dry cleaners, boilers, printers, auto spray booths, etc.
5. If a Health Risk Screening Assessment (HRSA) was completed for the source, the application number will be listed here.
6. The date that the HRSA was completed.
7. Engineer who completed the HRSA. For District purposes only.
8. All HRSA completed before 1/5/2010 need to be multiplied by an age sensitivity factor of 1.7.
9. The HRSA "Chronic Health" number represents the Hazard Index.
10. Further information about common sources:
   a. Sources that only include diesel internal combustion engines can be adjusted using the BAAQMD's Diesel Multiplier worksheet.
   b. The risk from natural gas boilers used for space heating when <25 MM BTU/hr would have an estimated cancer risk of one in a million or less, and a chronic hazard index of 0.003 or less. To be conservative, requestor should assume the cancer risk is 1 i
   c. BAAQMD Reg 11 Rule 16 required that all co-residential (sharing a wall, floor, ceiling or is in the same building as a residential unit) dry cleaners cease use of perc on July 1, 2010. Therefore, there is no cancer risk, hazard or PM2.5 concentrations from co-residential dry cleaning businesses in the BAAQMD.
   d. Non co-residential dry cleaners must phase out use of perc by Jan. 1, 2023. Therefore, the risk from these dry cleaners does not need to be factored in over a 70-year period, but instead should reflect the number of years perc use will continue after t
   e. Gas stations can be adjusted using BAAQMD's Gas Station Distance Mulitplier worksheet.
   f. Unless otherwise noted, exempt sources are considered insignificant. See BAAQMD Reg 2 Rule 1 for a list of exempt sources.
   g. This spray booth is considered to be insignificant.

Bay Area Air Quality Management District

Risk & Hazard Stationary Source Inquiry Form

This form is required when users request stationary source data from BAAQMD. This form is to be used with the BAAQMD's Google Earth stationary source screening tables.

For guidance on conducting a risk & hazard screening, including for roadways & freeways, refer to the District's Risk & Hazard Analysis flow chart.

Also see the District's Recommended Methods for Screening and Modeling Local Risks and Hazards document.

Table A: Requestor Contact Information	
Contact Name:	James A. Reyff
Affiliation:	Illingworth & Rodkin, Inc.
Phone:	707-766-7700
Email:	jreyff@illingworthrodkin.com
Date of Request	4/9/2012
Project Name:	Regional Groundwater Storage and
Address:	various
City:	
County:	
Type (residential, commercial, mixed use, industrial, etc.):	Public Works - Pump Stations
Project size (# of units, or building square feet):	<3,000 sf
Comments:	

For Air District assistance, the following steps must be completed:
Complete all the contact and project information requested in Table A. Incomplete forms will not be processed. Please include a project site map.
Download and install the free program Google Earth, http://www.google.com/earth/download/ge/, and then download the county specific Google Earth stationary source application files from the District's website, http://www.baaqmd.gov/Divisions/Planning-and-Research/CEQA-GUIDELINES/Tools-and-Methodology.aspx. The small points on the map represent stationary sources permitted by the District (Map A on right). These permitted sources include diesel back-up generators, gas stations, dry cleaners, boilers, printers, auto spray booths, etc. Click on a point to view the source's Information Table, including the name, location, and preliminary estimated cancer risk, hazard index, and PM2.5 concentration.
Find the project site in Google Earth by inputting the site's address in the Google Earth search box.
Using the Google Earth ruler function, measure the distance in feet between the project's fenceline and the stationary source's fenceline for all the sources that are within 1,000 feet of the project's fenceline. Verify that the location of the source on the map matches with the source's address in the Information Table, by using the Google Earth address search box to confirm that the source is within 1,000 feet of the project. Please report any mapping errors to the District (District contact information in Step 9).
If the stationary source is within 1,000 feet of the project's fenceline and the stationary source's information table does not list the cancer risk, hazard index, and PM2.5 concentration, and instead says to "Contact District Staff", list the stationary source information in Table B Section 1 below.
Note that a small percentage of the stationary sources have Health Risk Screening Assessment (HRSA) data INSTEAD of screening level data. These sources will be noted by an asterisk next to the Plant Name (Map B on right). If HRSA values are presented, these values have already been modeled and cannot be adjusted further.
Email this completed form to District staff (Step 9). District staff will provide the most recent risk, hazard, and PM2.5 data that are available for the source(s). If this information or data are not available, source emissions data will be provided. Staff will respond to inquiries within three weeks.
Note that a public records request received for the same stationary source information will cancel the processing of your SSIF request.
Submit forms, maps, and questions to Alison Kirk at 415-749-5169, or akirk@baaqmd.gov .
